$$\sigma_1(\widehat{\mathbf{D}}, \mathbf{X}) = \left(\frac{\sum_{i=2}^{n} \sum_{j=1}^{i-1} w_{ij} \left(\widehat{d}_{ij} - d_{ij}(\mathbf{X}) \right)^2}{\sum_{i=2}^{n} \sum_{j=1}^{i-1} w_{ij} d^2_{ij}(\mathbf{X})} \right)^{1/2} \qquad [3]$$

The configurations $\mathbf{X}$ and the $\widehat{d}_{ij}$'s obtained by minimizing normalized Stress and Stress-1 only differ by unimportant overall scaling constants (for proofs, see, e.g., Section 11.1 of Borg and Groenen, 2005). When using MDS, Stress-1 is almost always reported as a fit index, because it is comparable over different solutions due to its normalizing denominator. Hence, when reading 'Stress' in MDS publications, it can be assumed to mean 'Stress-1.'

Similarities, Dissimilarities, and Optimal Transformations

If the proximity data are similarities s_{ij}, they first need to be transformed into dissimilarities (either 'by hand' or within the MDS program). A simple scale reversal is accomplished by

Figure 3 Shepard diagram for **Figure 1**; black points show $(\delta_{ij}, \widehat{d}_{ij})$ pairs; gray open circles show $(\delta_{ij}, d_{ij}(\mathbf{X}))$ pairs; vertical distances of black and gray points are errors of representation.

$\delta_{ij} = c - s_{ij}$, where $c = \max_{ij}(s_{ij})$. A second way of transforming s_{ij} into δ_{ij} exists if all $s_{ij} > 0$. Then choosing $\delta_{ij} = 1/s_{ij}$ is often a good choice. In the value study described above, the correlations r_{ij} were transformed into dissimilarities by $\delta_{ij} = (1 - r_{ij})^{1/2}$, a conversion turning correlations into Euclidean distances.

MDS converts these dissimilarities further into $\widehat{d}_{ij}$'s (d-hats), that is, admissibly rescales them on their scale level so that they differ as little as possible from the distances of the MDS configuration $\mathbf{X}$. The d-hats for the final MDS solution in **Figure 1** are visualized in the *Shepard diagram* in **Figure 3** by the black points. The vertical distance between a gray point (representing the distance $d_{ij}(\mathbf{X})$ in this plot) and the corresponding black point (representing the $\widehat{d}_{ij}$) shows the error of representation of the MDS solution for the object pair ij. If both points (black and gray) are close, then there is little error, and if they are far from each other, the error is large. The Shepard diagram in **Figure 3** shows that there is little scatter of the gray points about the black-point trend. Hence, the MDS solution represents the structural information contained in the proximity data quite well.

A Brief History of MDS

MDS was not invented by statisticians. The main reason for its existence is that psychologists used the distance formula as a model of perception and judgment. They argued that if a judgment on the similarity of two objects is needed, the person first forms a mental representation of the objects in 'psychological space,' a space spanned by the objects' subjective attributes. Dissimilarity judgments are then generated by first assessing the differences of the objects on each attribute, and then summing these intradimensional differences over the dimensions. To the outside observer – and possibly also to the person himself or herself – the psychological space itself may be unknown, but MDS promised to 'uncover' it from the individual's overall dissimilarity judgments. When it became technically feasible to run MDS with ordinal similarity data in the 1960s, this model led to much research.

Ordinal MDS with its flexibility to analyze all kinds of proximity data became popular because computer programs became widely available that solved the complex mathematics of this scaling model. Ordinal MDS dominated the field for many years, but interval and even ratio MDS later recovered considerably in terms of utilization. This had statistical reasons on the one hand (ratio MDS solutions, for example, are often less cluttered), and theoretical reasons on the other hand (the emphasis of measurement foundations had shifted toward cumulative theory construction over replications, away from an almost endless testing of single data sets), and metric MDS solutions often allow for simpler and more robust interpretations than possibly overfitted ordinal solutions. Today, ordinal MDS is but one of several MDS models. Advanced computer programs generate solutions for each of them almost instantaneously, and so they can be tested easily against each other at virtually no costs.

Many of the original motives that led to the development of MDS have become unimportant. What has survived, in particular, is using MDS in attitude and value research, for example, where intercorrelations of survey items are studied for correspondences of the conceptual facets of the items to regions of their spatial representation (as in **Figure 1**). However, most recent applications of MDS serve a much wider purpose, that is, they are done to visualize tables of indices that can be interpreted as (dis)similarity data. For that purpose, MDS is highly useful as it can handle a vast variety of data as long as they are (dis)similarities (e.g., correlations, covariances, co-occurrence data, profile distances); it does not require interval-scaled data but also handles ordinal (and even nominal) data; it is robust against missing data and coarse data; it often serves as a data smoother, showing a structure that is replicable even under conditions of high error; it is easily explained to nonexperts and allows them to explore the solutions without much risk; it is easy to run for nonexperts even though its solution algorithms are rather difficult; and it does not impose a particular interpretation of its solution onto the user but allows the data to speak for themselves.

Data Used in MDS

MDS builds on *proximity* data that express the similarity or the dissimilarity among objects of interest. In psychological research, proximities are often collected directly by asking persons to rate the perceived similarity of objects of interest on a numerical rating scale. A popular alternative is sorting a stack of cards. Each card exhibits exactly one pair of objects. The testees are asked to sort these cards such that the card with the most similar pair is on top of the stack, and the card showing the most dissimilar pair at the bottom. This sorting can be further simplified: The testee is asked to begin by sorting the cards into only two stacks, one for the 'similar' pairs of objects, and one for the 'dissimilar' pairs. For each stack, this two-stack

sorting is repeated several times until the testee feels that he/she cannot reliably split the remaining stacks any further. One then numbers the various stacks from most similar to least similar. Pairs in the same stack receive this stack's number as a similarity score.

Pairwise procedures can lead to a huge number of pairs that must be judged by the subjects. Fortunately, not all these pairs are needed, because MDS also works with missing data. Spence and Domoney (1974) showed that the proportion of missing data can be as high as 80% and (ordinal) MDS is still able to recover an underlying MDS configuration quite precisely, given certain side constraints such as randomly distributed missing values in the data matrix and 'many' points. One can further improve the robustness of MDS by paying particular attention to collecting proximities for pairs of objects that seem very dissimilar rather than similar, because data that correspond to large distances are particularly important for recovering an underlying true MDS configuration (Spence and Graef, 1974).

The labor involved in data collection can also be reduced by simplifying the similarity judgments. Rather than asking for graded ratings on, say, a 10-point scale, one may offer only two response categories, 'similar' and 'dissimilar' for each pair of objects. Summing such data over replications or over respondents leads to *confusion frequencies* or, after dividing by the number of cases, to *confusion probabilities*. Yet, such aggregations are not necessarily required. Green and Wind (1973) showed that robust MDS works well even with using coarse data such as 1-0 data or ratings with few categories (given advantageous side constraints such as scaling in the true dimensionality and having many points).

Today, most applications of MDS are based on proximity indexes derived from pairs of data vectors. The typical case is correlating the objects of interest over their ratings on certain attributes. So, for example, rather than asking a person to rate the global similarity of two countries such as 'Japan and China,' we could ask them to first rate each country on attributes such as size, population, Gross National Product (GNP), etc., and then compute the correlation of these countries over these attributes.

Rather than using correlations, one can also measure their overall dissimilarity by a distance function such as the Euclidean distance. If ordinal MDS is employed, it becomes irrelevant whether product–moment correlations or Euclidean distances are used, because they are monotonically related and the rank order of the data is all that matters in ordinal MDS. If interval or ratio MDS is used, however, or if other distance functions are used, then one has to consider carefully which coefficient is best to express the similarity of profiles in the desired sense.

An interesting special case of proximities are *co-occurrence data*. Here is one example. Coxon and Jones (1978) studied the categories that people use to classify occupations. Their subjects were asked to sort a set of 32 occupational titles (such as barman, statistician, and actor) on the basis of their overall similarity into as many or as few groups as they wished. The result of this sorting can be expressed, for each subject, by a 32×32 *incidence matrix*, with an entry of 1 wherever its row and column entries were sorted into the same group, and 0 elsewhere. The elements of this incidence matrix, thus, are based on directly collected same-different proximities.

Co-occurrence data are typically aggregated over persons. This is done by first adding the various combinations of occurrence, nonoccurrence, and co-occurrence of any two events, X and Y, of the set of events of interest. Each event either occurs ($= 1$), or it does not occur ($= 0$). We denote the frequencies of the various combinations by 11, 10, 01, and 00, respectively. This leads to an amazing number of different similarity measures (Gower and Legendre, 1986). A prominent example is $S_2 = 11/(11 + 10 + 01 + 00)$. Another case is $S_3 = 11/(11 + 10 + 01)$ (Jaccard similarity index). A third example is $S_4 = (11 + 00)/(11 + 10 + 01 + 00)$. Choosing a particular S-index over another such index can have dramatic consequences. Rare events, for example, boost 00 so that S_4 makes two events similar just because they are rare.

Basic Formal Aspects of MDS that the User Should Know

Stress Values

The fit of an MDS solution can be evaluated by considering the Stress value. The dominant Stress measure in the literature is Stress-1 which we report here. The solution in **Figure 1**, for example, has a Stress value of 0.15. (Stress = 0.00 means perfect fit; the worst possible Stress value is 1.00.) This value is often compared with the Stress expected for purely random data. Simulation studies by Spence and Ogilvie (1973) show that for an ordinal MDS configuration of 40 points in two dimensions, the expected Stress is about 0.35, with a standard deviation of 0.003. Hence, our solution in **Figure 1** is highly significant, at least when tested against this criterion, that is, against the "nullest of all null hypotheses" (Cliff, 1973).

In general, when evaluating the Stress of an MDS solution, many factors have to be considered, namely

- The greater the number of points n, the larger the expected Stress.
- The greater the dimensionality of the MDS solution, the smaller the expected Stress.
- The greater the noise in the data, the larger the expected Stress.
- The stricter the transformation, the higher the expected Stress value: ratio > interval > ordinal.
- For ordinal transformations and the primary approach to ties, the more ties (= equal values) in the proximities, the smaller the expected Stress.
- The more proximities are missing, the easier it is to find an MDS solution with small Stress.
- Eliminating particular points that contribute highly to Stress or setting certain proximities as missing (e.g., because they are errors) can reduce the total Stress considerably.

Dimensionality of the MDS Solution

In terms of dimensionality, the vast majority of MDS solutions in the literature are two-dimensional. When exploring a set of data, scaling in two dimensions is always the first option, because such a solution is easily accessible to the researcher's eye and often sufficiently detailed for analyzing the essential (and robust) structure of the proximities. Points that do not fit

at all into this plane ('outliers') could be eliminated at first, and later studied in higher-dimensional MDS spaces or by other statistical methods in terms of how they relate to all the variables that do fit.

Interpreting MDS Solutions

Interpreting an MDS solution can be understood as projecting given or assumed content knowledge onto the MDS configuration. Any feature of the MDS geometry can be interpreted. Three methods can be helpful: directions, regions, and clustering of points. Interpreting directions has been most popular, particularly directions that coincide with dimensions. Often, it is more useful to interpret a direction that is not the same as a dimension. Figure 2 gives an example. The two directions (e.g., self-enhancement vs self-transcendence) are interpreted by studying the projections of the points on these lines from a content perspective.

Even more general is interpreting *regions* as in Figure 1. Regions are subsets of points of an MDS space that are connected (i.e., each pair of points in a region can be joined by a curve whose points lie completely within this region), nonoverlapping, and exhaustive (i.e., each point lies in exactly one region). Such regions may arise when first projecting some codes onto the points, and then *partitioning* the space so that regions emerge where all points have the same code. In Figure 1, all points were first coded by the value that it is related to (power, security, etc.). Then, a set of lines were drawn into this plot so that 10 different regions emerged. Rather than choosing curved lines, all lines are straight here, and all lines emerge from one common origin. This circumplex structure was chosen because it replicates what was found in many previous studies on value research. There are a few points in a 'wrong' (but neighboring) region, but this can be interpreted as due to noise in the data. Three prototypical regionalities that often arise in practice are shown in Figure 4: *axial*, *modular*, and *polar* partitions. Different partitionings can be superimposed to yield two- or multiway partitionings. A prominent example is the *radex*, a combination of a circumplex and a set of concentric regions, all emanating from a common origin. The radex, therefore, is a pattern of regions that looks like a dartboard. It adds to a circumplex a polar facet that explains the points' distance from the origin.

Regions are sometimes confused with *clusters*. Clusters, however, are but special cases of regions. They are often defined as lumps (or chains) of points surrounded by empty space so that each point in a cluster is always closer to at least one point within the cluster than to any point not in the cluster.

Doing It Right

As with other techniques, MDS users need to pay special attention to some practical details.

If an MDS program assumes the wrong polarity for the data, it almost always generates uninterpretable solutions with very high Stress. No computer program can find out by itself whether the proximity data are similarities or dissimilarities. Thus, it is crucial to read in data whose meaning corresponds to the program's default assumption, or click the correct 'similarity' or 'dissimilarity' button when running the program.

As the distances are the most important output of MDS, they should not get distorted in the configuration plots. The MDS user should therefore check that the plot has an aspect ratio of 1, that is, one horizontal unit should be equal to one vertical unit. Many plotting programs try to maximize the spread of the points along the horizontal and vertical axes, thereby destroying the aspect ratio of 1. This even happens in the plots provided by some MDS programs.

As MDS is an iterative method, it can be stopped too early causing the solution to be suboptimal. Therefore, the maximum number of iterations may need to be increased and subsequent Stress-1 values should be smaller than 0.0 001 or subsequent normalized Stress smaller than 10^{-8}. In addition, it is helpful to start the iterations with a good initial configuration. A particularly good one invariably available in MDS programs is the classical MDS start also referred to as 'Torgerson' scaling.

The minimization algorithms can get stuck in a local minimum which is not the global minimum. To guard against such local minima, some programs offer multiple random start configurations. Often, a good initial start also leads to good local minima.

A particularly bad situation of local minima occurs in the case of *unidimensional* scaling ($m = 1$). It can be proven that this is a notoriously hard combinatorial problem. Unless severe precautions are taken (such as a massive number of random starts) the user is advised not to use standard MDS software as it is very likely that it will end in a poor-quality local minimum.

The most uninformative data for MDS consist of all dissimilarities (or d-hats) being the same. It turns out that in this situation, MDS finds special solutions. For $m = 1$, the solution consists of all points equally spaced on a line; for $m = 2$, the points will be distributed in concentric circles; for

Figure 4 Prototypical partitioning of multidimensional scaling configurations by three facets, each one with three categories (a, b, c).

$m > 2$, the points will be on the surface of a hypersphere. Although constant dissimilarities do not occur without the user knowing this, almost constant d-hats can occur during the optimization process. Therefore, the user should always check the Shepard diagram and consider whether the d-hats found have sufficient spread around their mean. With little spread, the solution in two dimensions will be the uninformative circle of almost randomly spread points. Also, if n is large and the distribution of dissimilarities is more skewed then, too, the MDS solution tends to show the uninformative constant dissimilarity solution.

Weights w_{ij} cannot only be used for handling missing values. Another use is to selectively emphasize or de-emphasize the fit of certain dissimilarities. A useful choice is setting $w_{ij} = \delta_{ij}^{q}$. For large q (e.g., $q = 5$), only the large dissimilarities will determine the shape of the MDS solution. In contrast, choosing q small (e.g., $q = -5$) emphasizes the fit of the smaller dissimilarities so that the distances representing the larger ones may well be poorly represented.

Special weighting patterns exist such that two or more subsets of objects can be formed that are not connected by a single dissimilarity. This situation is called *reducible* because the MDS problem could be split up into as many separate MDS solutions as there are subsets. Such a reducible situation can occur if there are many missing values. As there are no connections between the subsets, there is no use in presenting the objects of different subsets in a single plot and it is better to represent each subset in a separate plot.

Special Cases of MDS

Confirmatory MDS

Standard MDS does not impose restrictions to the configuration **X**. However, if additional information is available or can be theorized, it may be useful to impose constraints on the configuration **X**. Here is a classical example, the MDS of Morse signals. Content information is available on the Morse signals: Each signal has a temporal length (from 0.05 to 0.95 s) and a certain composition of long and short beeps. We code the latter as 'only short beeps' (1), 'more short beeps than long beeps' ($1 > 2$), 'an equal number of short and long beeps' ($1 = 2$), 'more long than short beeps' ($2 > 1$), and 'only long beeps' (2). These two external variables are facets of the signals. An approximate axial partitioning of the unconstrained MDS representation of confusion rates of Morse signals is shown in Figure 5(a). The 'curvy' partitioning lines in this plot were drawn by hand. Figure 5(b) shows the confirmatory solution. Here, the partitioning lines are all straight lines, a property enforced onto the MDS configuration. The axially constrained ('confirmatory') solution has a slightly higher Stress (0.21) compared to the unconstrained solution (0.18), yet it yields a plot that is much easier to interpret in psychophysical terms. Moreover, the linearized structure expresses two simple laws of formation and, therefore, it can be expected to be more robust over replications than the possibly overfitted exploratory MDS pattern with its curvy partitioning lines that were inserted only afterward.

An alternative form of confirmatory MDS is the spherical (in 3D) or the circular constraint (in 2D). The points in Figure 2 are almost on a perfect circle. Therefore, imposing the circular restriction will hardly increase the Stress while making the MDS model more parsimonious.

At this time, the possibilities to impose certain constraints onto **X** are rather limited. For example, it would be desirable to request that the pattern in Figure 1 emerges as a perfect circumplex with no misplaced points, possibly also with a particular order of the various value regions. Yet, solutions or programs for such constraints have not been worked out yet.

In general, the stronger the constraints, the higher the increase in Stress compared to the unconstrained solution. However, if the increase is large then one should doubt

Figure 5 Multidimensional scaling (MDS) solution of ordinal MDS on the Rothkopf confusion data with regions drawn by hand (panel a) and regionally constrained MDS (panel b). The panels in this figure are reproduced from Borg, I., Groenen, P.J.F., 2005. Modern Multidimensional Scaling, second ed. Springer, New York, with kind permission from Springer Science and Business Media B.V.

whether the dissimilarities can be properly modeled by an MDS with the chosen constraints.

Three-Way MDS

Several models have been introduced for dealing with replications of the dissimilarity matrix. One particularly well-known example is the *dimensional weighting model*, often called the INDSCAL model ('individual differences scaling model') of Carroll and Chang (1970).

$$d_{ijk}(\mathbf{X}, \mathbf{w}_k) = \left(\sum_{s=1}^{m} w_{sk} (x_{is} - x_{js})^2 \right)^{1/2}, \quad w_{sk} > 0 \qquad [4]$$

where the parameter $k = 1, \ldots, K$ stands for different individuals or cases. The weight w_{sk} can be interpreted as the *salience* of dimension s for person k. Expressed geometrically, different individuals share a common space $\mathbf{X}$ but they may differ in how they weight the dimensions of this space. Applying the weight w_{sk} in [4] amounts to stretching or compressing $\mathbf{X}$ along dimension s for individual k. Although this is an interesting model, it tends to promise more than it holds. The problem is that one cannot infer from $2 \cdot w_{1k} = w_{2k}$, for example, that individual k attributes twice as much weight to dimension 2 than to 1, because these weights depend on the norming of $\mathbf{X}$: If we stretch or compress $\mathbf{X}$ along its dimensions, the weights change inversely. What can be compared, though, are the weights of different individuals *within* each dimension.

Unfolding

None of the 151 individuals of the introductory example appeared in the MDS solutions in Figures 1 and 2. Rather, all individuals got 'lost' in the correlations that were used for MDS. So, one can ask if the circle of values also exists within individuals. To answer this question, we use *unfolding*, a special case of MDS. In *external unfolding*, we would attempt to represent each individual by adding one particular point to the configuration in Figure 2. This *person point* should be located so that the distances from this point to the *value points* correspond to this person's importance scores. For example, if a person assigns a high importance value to power, his or her person point should be close to the point representing power in Figure 2 (PO). If security is rated as not so important, this person point should be far from the point representing security in Figure 2 (SE).

Unfolding can also be computed directly, without using any previously generated configurations. To do that, we first reverse the importance scores by turning them into dissimilarities by subtracting each importance rating from the largest observed importance score. In *metric unfolding*, we then search for a configuration with 10 points for the 10 values and 151 points for the 151 individuals such that the distances between the person points and the value points directly match the dissimilarities (except for an overall scaling factor). Figure 6 shows the result. The 10 value points are represented by their acronyms, and the 151 person points by small circles. The value points, again, show an approximately circular structure, with values ordered as predicted by the Schwartz value theory.

Figure 6 Metric unfolding solution for the relative importance scores given by 151 persons to 10 universal values. PO, power; AC, achievement; HE, hedonism; ST, stimulation; SD, self-direction; UN, universalism; BE, benevolence; TR, tradition; CO, conformity; SE, security.

The unfolding solution has a good fit to the data. Almost all persons are well represented. An exception is a person who rates achievement as not so important and power as very important, for example. This person's point should therefore be far from AC and close to PO. However, in Figure 6, AC and PO are close together, and so this person's ratings cannot be perfectly modeled within the value configuration shown in Figure 6.

Software

MDS can be run in almost all statistical software packages. The two most dominant ones are the smacof package in R and Proxscal in SPSS. For an overview of available MDS software with syntax, see Borg and Groenen (2005) and Borg et al. (2013). The GGvis software within GGobi (either stand alone or callable as an R package) of Buja and Swayne (2002) is one of the very few MDS software packages that is truly interactive. Vosviewer is MDS software (and more) with very good graphics for the analysis of bibliometric data (Van Eck and Waltman, 2010).

Metric unfolding can be done by any MDS program that allows for missing values. The reason is that unfolding can be seen as a special case of MDS where the objects can be split into two sets and the within-set proximities are missing. However, nonmetric unfolding requires special software to avoid degenerate solutions where one of the sets collapses into a single point. At the time of writing, the only software that can handle nonmetric unfolding is Prefscal (in SPSS).

Further Reading

Quite comprehensive treatments of MDS and related techniques can be found in Cox and Cox (2000) and Borg and Groenen (2005). An introductory text on MDS is Borg et al. (2013). A recent paper on MDS for statisticians is Buja et al.

(2008). For the majorization algorithm for MDS (smacof and Proxscal) we refer to De Leeuw and Heiser (1980) and De Leeuw (1988) or Borg and Groenen (2005).

Multilevel Models in Demography

Germán Rodríguez, Princeton University, Princeton, NJ, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

We introduce multilevel models in demography, reviewing random intercept and random slope models, cross-level interactions, estimation of the fixed and random parameters, and calculation of subject-specific and population-average predictions. All ideas are discussed in the context of specific applications, a two-level analysis of contraceptive use in 15 countries and a three-level hazard model of infant and child survival in Kenya, with emphasis on the interpretation of results. Throughout the article we include references to other demographic applications of interest.

Introduction

Multilevel models deal with the analysis of data collected at multiple levels of aggregation, such as surveys that collect data on children, their mothers, and the communities where they live. Accounting for the correlation structure of the data is important for correct inference, and multilevel models achieve this aim by introducing stochastic residuals at various levels. The models are also known as *hierarchical*, because the levels are usually nested, and as *mixed*, because they include fixed and random parameters. They also encompass as special cases many models for longitudinal and panel data.

Although there were precursors going back to the 1950s, and significant statistical work in the 1970s, the field of multilevel analysis really took off in the 1980s with the publication of a number of research papers, many motivated by school effectiveness studies, see de Leeuw and Meier (2008). The field of demography was present from the outset, with Wong and Mason (1985) developing a hierarchical logistic regression model to study contraceptive use in 15 countries using data from the World Fertility Survey (WFS), see also Entwisle et al. (1986).

Multilevel analysis came of age in the 1990s, with the development of software packages and book-length treatments by Goldstein (1995) and collaborators, who developed MLn/MLwiN; Bryk and Raudenbush (1992), who developed HLM; and Longford (1993), who wrote VARCL. In the next 20 years, the field continued to advance, and multilevel procedures were incorporated in standard statistical packages, most notably Stata, which includes in version 13 a newly expanded family of multilevel procedures documented in a separate manual (StataCorp, 2013), and R, with functions contributed by Pinheiro and Bates (2000) and Bates (2010).

Estimation in linear mixed models is fairly straightforward, as these are essentially linear models with a patterned variance–covariance matrix, often block diagonal reflecting the hierarchical structure of the data. A common algorithm alternates between estimation of the linear parameters given the variance matrix, and estimation of the parameters in the variance matrix given the linear predictor, using generalized least squares in each step. There are two approaches in current use, maximum likelihood (ML) and restricted maximum likelihood (REML), which differ in the choice of contrasts used to estimate the variance parameters. REML has better small sample properties, but cannot be used to compare nested models that differ in the linear predictor, so ML has wider applicability.

Estimation in generalized linear mixed models, such as multilevel logit or hazard models, is not so straightforward because the resulting likelihoods are intractable. This has lead authors to propose approximate estimation procedures, most notably maximum quasi-likelihood and penalized quasi-likelihood, with linear and quadratic variants. Unfortunately these approximations are not reliable, as shown by Rodríguez and Goldman (1995), see also Lin and Breslow (1996). For models involving a moderate number of random effects the best approach is to use Gaussian quadrature, preferably one of the adaptive variants proposed by Liu and Pierce (1994) and Rabe-Hesketh et al. (2002). For models involving a large number of random effects one must resort to Markov chain Monte Carlo (MCMC) procedures in a Bayesian framework, see Clayton (1996). For a comparison of likelihood and Bayesian procedures, see Browne and Draper (2006).

Most demographic applications of multilevel models involve binary, categorical, count, or survival data, rather than continuous responses. We will, therefore, skip the linear case and focus directly on multilevel generalized linear models. Instead of discussing these models in purely abstract terms, however, we will discuss them in terms of two demographic applications to help ground the ideas: a classic analysis of ever use of contraception in 15 countries using random-coefficient logit models, and an analysis of infant and child mortality using survival models with shared frailty at the family and community levels. Along the way we include pointers to the literature and to other demographic applications. A useful general reference on multilevel modeling is Rabe-Hesketh and Skrondal (2012).

Multilevel Models of Contraceptive Use

We will introduce multilevel logit models in terms of the classic model of Wong and Mason (1985), who studied ever-use of contraception among women aged 40–44 years in 15 WFS countries. We build the model step-by-step, introducing random intercepts, random slopes, and cross-level interactions, before turning to interpretation of the estimates.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.31024-8

Let π_{ij} denote the probability of having ever used contraception for the i-th woman aged 40–44 years in the j-th country. We start from a standard logit model

$$\text{logit}(\pi_{ij}) = \alpha + \beta x_{ij}$$

where x_{ij} is an individual-level predictor, such as education or type of place of residence. One problem with this model is that the observations will not be independent if women in each country share unobserved characteristics.

Random Intercepts

We address this problem by introducing a country-level residual and by assuming that conditional on that residual the observations are independent and follow the logit model

$$\text{logit}(\pi_{ij}) = (\alpha + a_j) + \beta x_{ij} \qquad [1]$$

where the random effect $a_j \sim N(0, \sigma_a^2)$ captures variation across countries in levels of contraceptive use, net of the observed covariates.

In this model the observations are still independent across countries but are correlated within each country. The intraclass correlation coefficient can be extended to logit models in terms of a latent variable representing propensity to have used contraception, and is defined as

$$\rho = \frac{\sigma_a^2}{\sigma_a^2 + \pi^2/3}$$

where $\pi^2/3$ is the variance of the standard logistic distribution. Rodríguez and Elo (2003) proposed measures of intraclass correlation based on observable outcomes or manifest variables.

You may wonder why not introduce a separate dummy variable for each country. This is probably alright if you have just a few countries with large samples on each, but not if you have large numbers of groups with few observations per group, as is often the case with panel data. Consistent estimation of logit models then requires conditioning on a minimal sufficient statistic for the group totals, and leads to a so-called fixed-effects estimator, see Allison (2009).

There is an extensive literature, and more than a fair share of confusion, concerning the advantages and disadvantages of fixed- and random-effect estimators, and a thorough discussion would vastly exceed the scope of this article. A clear advantage of fixed-effect estimators, however, is that they focus on within-group variation and therefore adjust implicitly for any omitted group-level confounders. In contrast, random effects, like all statistical residuals, reflect only variation orthogonal to the observed covariates. As we will see below, however, multilevel models can be used to capture both within- and between-group variation and thus provide a richer modeling framework.

Random Slopes

The next model we will consider allows the effect of an individual-level covariate to vary across contexts, so the slope becomes random as well,

$$\text{logit}(\pi_{ij}) = (\alpha + a_j) + (\beta + b_j)x_{ij} \qquad [2]$$

The level-2 residuals are assumed to have a bivariate normal distribution with unstructured variance–covariance matrix, so the intercept and slope can be correlated

$$\begin{pmatrix} a_j \\ b_l \end{pmatrix} \sim N\left(\begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} \sigma_a^2 & \sigma_{ab} \\ \sigma_{ab} & \sigma_b^2 \end{pmatrix}\right)$$

In their analysis of contraceptive use, Wong and Mason (1985) allowed the coefficients of years of education and childhood residence to vary across countries.

You may wonder why not run separate regressions for each country in the survey. Again, this is feasible if you have just a few large groups, but not if you have many small groups, where it is important to improve estimation for each group by borrowing strength from the others. As we will see, even with 15 countries there are substantial gains from a multilevel approach.

Level-Specific Models

An alternative way to write these models uses separate equations for each level, a practice that goes back to Burstein's (1980) slopes-as-outcomes ideas, and popularized by the specialized packages HLM and MLwiN. We specify the level-1 model as

$$\text{logit}(\pi_{ij}) = A_j + B_j x_{ij} \qquad [3]$$

where we use roman letters to indicate that the parameters are random and follow their own models.

In the random-intercept model, the level-2 equation is

$$\begin{aligned} A_j &= \alpha + a_j \\ B_j &= \beta \end{aligned}$$

In the random-slopes model, the level-2 equation is

$$\begin{aligned} A_j &= \alpha + a_j \\ B_j &= \beta + b_j \end{aligned}$$

You should verify that substituting these equations on [3] leads to [1] and [2]. Learning to do this translation is important because statistical packages differ in how models are specified.

Contextual Variables

We now expand the level-2 model to include a group-level predictor z_j, also called a contextual variable. We start from the slopes-as-outcomes model (3) and assume that the intercept and slope satisfy the level-2 models

$$\begin{aligned} A_j &= \alpha_0 + \alpha_1 z_j + a_j \\ B_j &= \beta_0 + b_j \end{aligned}$$

In other words, the baseline level of contraceptive use is a linear function of the contextual variable. If we substitute these equations in [3] we obtain

$$\text{logit}(\pi_{ij}) = (\alpha_0 + \alpha_1 z_j + a_j) + (\beta + b_j)x_{ij}$$

Thus, contextual variables are introduced in the linear predictor just like any other variable. The contextual predictors used in the analysis of contraceptive use were gross national product (GNP), an index of family planning effort (FPE) program, and their interaction.

Between and Within-Group Estimates

An important type of contextual variable is the group mean of an individual-level variable. It is perfectly possible to include in the model both the group mean $\bar{x}_j$ and the individual-level predictor, preferably as a deviation from the group mean $x_{ij} - \bar{x}_j$. In fact, there are often good reasons to do so. Specifically, consider the random-intercept model

$$\text{logit}(\pi_{ij}) = (\alpha + a_j) + \beta_B \bar{x}_j + \beta_W (x_{ij} - \bar{x}_j)$$

We use the subscripts B and W to emphasize that the coefficient of the group mean captures *between* group variation, and the coefficient of the individual predictor reflects *within* group variation. The within-group estimator is similar in spirit to a fixed-effects estimator and is usually very close in value (in fact, in linear models it is exactly the same). Moreover, it can be used in models that have no minimal sufficient statistic on which to base a fixed-effects estimator, including probit and negative binomial models. The random-effects estimator, obtained by omitting the group means, can be shown to be equivalent to a weighted average of the within- and between-estimators, and will obviously be appropriate (and more efficient) when the underlying parameters are the same. A test of $H_0{:}\beta_B = \beta_W$ is similar in spirit to a Hausman specification test; coefficients may be consolidated when the test accepts, or kept separate when the test rejects. For further discussion of this hybrid model, see Allison (2009) and Rabe-Hesketh and Skrondal (2012).

Cross-Level Interactions

The most general model allows the slope of an individual-level predictor to depend on a contextual variable, so the level-2 models become

$$A_j = \alpha_0 + \alpha_1 z_j + a_j$$
$$B_j = \beta_0 + \beta_1 z_j + b_j$$

If we substitute these equations in the basic model (3) we obtain

$$\text{logit}(\pi_{ij}) = (\alpha_0 + \alpha_1 z_j + a_j) + (\beta_0 + \beta_1 z_j + b_j) x_{ij}$$

And rearranging terms to collect the fixed and random coefficients we obtain

$$\text{logit}(\pi_{ij}) = (\alpha_0 + \alpha_1 z_j + \beta_0 x_{ij} + \beta_1 z_j x_{ij}) + (a_j + b_j x_{ij})$$

The fixed part of the model has main effects of the country- and individual-level predictors, as well as a *cross-level interaction* between country and individual, represented by the product $z_j x_{ij}$. The random part of the model depends on x_{ij}.

Wong and Mason (1985) allowed the coefficients of years of education and childhood urban residence to depend on GNP and FPE. Their final model, however, drops GNP and includes only one cross-level interaction between education and program effort, and is based on the following level-specific equations:

$$\text{logit}(\text{ever}_{ij}) = A_j + B_j\,\text{educ}_{ij} + C_j\,\text{urban}_{ij}$$
$$A_j = \alpha_0 + \alpha_1\,\text{fpe}_j + a_j$$
$$B_j = \beta_0 + \beta_1\,\text{fpe}_j + b_j$$
$$C_j = \gamma_0 + c_j$$

where the country-level residual (a_j, b_j, c_j) has a trivariate normal distribution with mean vector zero and unstructured variance–covariance matrix.

In words, the logit of the probability of ever use of contraception depends on the woman's years of education and childhood residence, the level and the education differential depend on the country's FPE, and all three coefficients have residual variation across countries.

Fixed Coefficients

The published estimates of the fixed parameters are reproduced in Table 1.

These coefficients can be interpreted in the usual way, exponentiating the estimates to obtain odds ratios. Thus, women who grew up in urban areas have 63% higher odds of having used contraception than women who grew up in rural areas, when we compare women with the same education who live in the same country. The coefficient of education requires some care because of the interaction with FPE. In countries with no program, each year of education is associated with 24% higher odds of ever use, everything else being equal. The education differential, however, is smaller at higher levels of effort, with an odds ratio of 1.157 at the mean level of effort (13) and an odds ratio of 1.092 at the highest observed level of effort (24). Finally, the odds of using contraception are higher in countries with higher levels of effort, with 9% higher odds per point of effort.

Variance Parameters

The random coefficients capture residual variation across countries in levels and differentials in ever use of contraception. The estimated variance–covariance matrix for these effects is presented in terms of standard deviations and correlations in Table 2.

We see substantial variation in levels of contraceptive use across countries after adjusting for observed covariates. I find it easier to interpret the results if we standardize the random

Table 1 Estimates of fixed coefficients

Variable	*Symbol*	*Coefficient*	*Standard error*	*Odds ratio*
Constant	α_0	−2.3695	0.4277	–
FPE	α_1	0.085	0.02685	1.088
Education	β_0	0.2147	0.03967	1.239
FPE × education	β_1	−0.005296	0.002416	0.995
Urban	γ_1	0.4909	0.1008	1.633

FPE = Family planning effort.

Table 2 Standard deviations and correlations of random effects

	Standard deviations		*Correlations*		
Variable	*Symbol*	*Value*	*Constant*	*Education*	*Urban*
Constant	σ_a	0.9017	1		
Education	σ_b	0.0681	−0.826	1	
Urban	σ_c	0.2419	−0.172	0.273	1

effects, so instead of $a_j \sim N(0, \sigma_a^2)$ we write $a_j = \sigma_a z_j$ where $z_j \sim N(0, 1)$. This shows that σ_a can be interpreted as an ordinary logit coefficient, exponentiating it to obtain an odds ratio. Thus, the odds of ever using contraception in a country that is one standard deviation above the mean are 2.5 times the odds for comparable women in the average country. Educational differentials also vary across countries from net of their level of effort and composition; the odds ratio per year of education in a country that is one standard deviation above the mean is 7% higher than in the average country. We also observe residual variation in urban–rural differentials, which are 27% larger in a country that is one standard deviation above the mean than in the average country, everything else being equal.

The correlations among the random effects are also interesting. Countries that have higher than expected ever use of contraception tend to have lower than expected differentials by education and, to a lesser extent, by childhood residence, net of their level of effort.

Empirical Bayes

We now consider estimating the random effects representing variation in levels and differentials across countries. In the context of our example, it would be useful to assess the extent to which ever use of contraception in a particular country is lower or higher than expected from its program effort and the education and childhood residence of its inhabitants. Similarly, we might be interested in ascertaining the extent to which the effect of education on ever use is larger or smaller than expected given its program effort. We contrast empirical Bayes (EB) and ML estimates.

The EB approach focuses on the posterior distribution of the random effects, which can be obtained from Bayes theorem as the product of the prior multivariate normal and the conditional likelihood or probability of the data given the random effects, which is product Bernoulli. The posterior depends on the regression coefficients and the variance–covariance matrix of the random effects. A full Bayesian analysis would assign prior (or hyper-prior) distributions to these as well. In contrast, an EB approach evaluates the posterior at the ML estimates of these parameters, and then takes the mean or mode. In logit models the calculation requires numerical integration.

An approach closer in spirit to ML uses the estimated linear predictor obtained by multiplying all predictors by their coefficients as an *offset* or known part of the model, and then estimates the random effects by running a separate regression in each group, in our example with education and urban as predictors. If one has few groups and they are reasonably large, it may be possible to simply run a separate regression in each group, which is what was done in this case, but the previous approach has wider applicability. For further details, see Rabe-Hesketh and Skrondal (2012).

Typically the Bayes estimates are closer to the mean than the corresponding ML estimates, a common property of Bayesian estimates known as 'skrinkage.' **Figure 1** illustrates this phenomenon by comparing EB and ML estimates of the urban–rural differential. The figure omits Kenya, where the initial estimate of nearly 2 was pulled all the way down to 0.7, much closer to the average. The EB estimates were also skeptical of the negligible or reverse differentials in Panama and Indonesia and pulled them up. The other countries show smaller differences, with EB estimates usually closer to the mean than ML. Generally speaking, EB estimates represent a compromise between having a separate estimate of the urban–rural differential for each country, and having a common estimate for all, with more weight given to the separate estimates where there is more information.

Predicted Probabilities

In logit models it is often useful to translate results into predicted probabilities, which are more easily understood than odds ratios. With multilevel models, results can be translated into two types of predicted probabilities: subject specific and population average. We illustrate by predicting ever use of contraception by childhood residence.

Figure 1 Estimates of urban–rural differential in ever use.

Subject-specific or conditional probabilities apply to an individual at given values of the fixed and random predictors, and can be easily obtained from the fitted equations. Calculations are typically done varying one variable while keeping all other predictors set to their means. In our case, we consider women who grew up in rural and urban areas have average education (3.43 years), and live in an average country, with an effort index of 13 and average unobserved characteristics. The linear predictor, excluding the urban coefficient, is $-2.3695 + 0.085 \times 13 + (0.2147 - 0.0053 \times 13) \times 3.43 = -0.7644$. The predicted urban and rural probabilities are thus

$$\text{logit}^{-1}(-0.7644) = 0.3177 \quad \text{and}$$
$$\text{logit}^{-1}(-0.7644 + 0.4909) = 0.4320$$

Population-average or marginal probabilities apply to an individual at given values of the fixed predictors but averaging over all random effects. In our example, we set childhood residence to rural and urban while keeping education and effort set to their mean values, but average over all country-level residuals. The calculations involve integrals of the form

$$\iiint \text{logit}^{-1}(-0.7644 + a + 3.43b + (0.4909 + c)u\phi(a,b,c)\,da\,db\,dc$$

where u is an indicator of urban childhood residence, and $\phi(a,b,c)$ is the trivariate normal density with mean zero and variance–covariance matrix given in **Table 2**. This integral can be approximated using Gaussian quadrature or by Monte Carlo integration, and leads to ever use estimates of 0.3347 for rural and 0.4399 for urban. In this case, the two kinds of predicted probabilities are very similar. The urban–rural differential in ever use averaged over countries is 0.105, compared to 0.114 in the average country. As usual, the marginal effect is smaller in magnitude than the conditional effect.

Running a logistic regression using generalized estimating equations, or an ordinary logit model that ignores the grouping but corrects the standard errors for clustering, produces population average estimates. A multilevel model can, of course, produce both.

Bibliographic Remarks

There are many applications of multilevel models to categorical outcomes in demography. Pebley et al. (1996) use three-level logit models to study prenatal care and childhood immunization in Guatemala. Rodríguez and Goldman (2001) use the same data as a case study to compare various estimation methods, including MCMC using the Gibbs sampler. Steele et al. (1999) look at the impact of family planning service provision on contraceptive use in Morocco. Ng et al. (2006) illustrate simulated ML using contraceptive prevalence data from Bangladesh. The data are used as an example in the Stata manuals and are therefore available for download. Mills and Begall (2010) look at intention to have a third child in 24 countries using a random-intercept-ordered logit model, which includes a cross-level interaction between a country-level gender gap index and the sex of the previous child. In a somewhat different vein, Schmertmann et al. (2013) estimate total fertility for many small areas in Brazil using a novel combination of EB estimates to smooth age-specific fertility rates with a Brass P/F correction adapted to work when fertility is declining rapidly.

Multilevel Models of Infant and Child Survival

Multilevel survival models are particularly important in demography, extending the classic ideas of unobserved heterogeneity of frailty of Vaupel et al. (1979) to include components shared by members of a group. Many parametric and semiparametric survival models can be extended in this way, but most applications to date have focused on discrete-time models, fitted via the connection with logistic regression (Allison, 1982), or continuous-time models with piecewise constant hazard, fitted via the connection with Poisson regression (Holford, 1980; Laird and Olivier, 1981). These approaches often give similar results, although they focus on probabilities and rates, respectively.

We illustrate the ideas with an analysis of infant and child mortality in Kenya described in more detail in Rodríguez (2008). We use a continuous-time hazard model with frailty shared at the family and community levels, fitted to data from the 1998 Kenya Demographic and Health Survey (KDHS). The analysis focuses on all births in the 10 years preceding the interview, but excludes 170 pairs of twins and one set of triplets, which have higher mortality than singletons. The final sample consists of 10 878 births to 4939 women who live in 530 communities, defined in terms of the ultimate area units in the sample. A limitation of the data is that the community is based on current residence, but 81% of the births occurred to mothers who have never moved.

A Three-Level Hazard Model

Let $\lambda_{ijk}(t)$ denote the instantaneous hazard of death at age t for the i-th child of the j-th mother in the k-th community. We assume that the hazard depends on age t; a set of observed child, family, and community characteristics x_{ijk}; and unobserved family and community effects a_{jk} and a_k, so the conditional hazard is

$$\lambda(t|x_{ijk}, a_{jk}, a_k) = \lambda_0(t)\exp\{x'_{ijk}\beta + a_{jk} + a_k\}$$

where $\lambda_0(t)$ is the baseline hazard, β is a vector of fixed parameters representing effects of observed covariates, and $a_{jk} \sim N(0, \sigma_2^2)$ and $a_k \sim N(0, \sigma_3^2)$ are random effects representing unobserved family and community frailty.

For estimation purposes we assume that the baseline hazard is constant in intervals defined by cutpoints $0 = \tau_0 < \tau_1 < \ldots < \tau_D = \infty$ so that $\lambda_0(t) = \lambda_{0d}$ if $t \in (\tau_{d-1}, \tau_d)$. We have some flexibility in choosing our intervals because the KDHS recorded age at death in days for deaths in the first month, months for deaths in the first year, and years thereafter. Following some exploratory work we settled on 0, 1–5, 6–11, 12–23, and 24–59 completed months, so we capture more detail at ages where the hazard is changing more rapidly. We then split each observation into one episode for each interval visited, and count events and exposure in each episode. The

analysis sample, censored at age five, comprises 48 094 pseudo-observations.

The predictors include one community-level variable, type of place of residence, classified as urban or rural; one family-level variable, years of education of the mother, which we model using linear and quadratic terms centered at seven; and five variables at the level of the child, all well-known risk factors: gender, represented by an indicator for males; cohort, with an indicator for births in 1993 or later; age of mother, represented by linear and quadratic terms centered on age 25; birth order, which we tried modeling using indicators for births of various orders, but was better captured using linear and quadratic terms centered on three; and length of the previous birth interval, which was best captured as $(30 - i)_+$, a linear spline term that is zero for intervals in excess of 30 months and increases linearly as the interval gets shorter.

Fixed Coefficients

The three-level piecewise-exponential proportional-hazards model just defined can be fitted via multilevel Poisson regression, with the counts of events as outcome and the logarithm of exposure time in each episode as an offset, in a direct extension of the results of Holford (1980) and Laird and Olivier (1981). Estimation using ML via adaptive quadrature leads to the results summarized in **Table 3**.

Interpretation of the fixed coefficients proceeds in the usual fashion, exponentiating them so they represent hazard ratios. The shape of the spline and quadratic fits may be better appreciated in **Figure 2**. Obviously, the hazard declines very substantially with age of the child, with the risk at age one being 95% lower than in the first month of life. We estimate a 9% higher risk for males than comparable females at the same age, but this effect is not significant. Children born in 1993, or later, have *higher* risk than children born earlier, after adjusting for all other factors, indicating a deterioration of survival prospects in the late 1990s. The lowest risk by age of mother occurs at age 32, but increases rapidly for older and particularly younger mothers, reaching 40% higher risk at ages 22 or 42, and even higher levels at younger ages. Birth order is not significantly associated with child survival. It is possible that the excess risk often observed for first births has been captured by age of mother. Short birth intervals are strongly associated with poor infant and child survival, with the hazard increasing 4% for each month that the preceding interval falls short of 30 months. This translates into 24% higher risk for children born 2 years after a sibling, compared to those born after an interval of 2.5 years.

Let us turn now to the family and community variables. Mother's education has a strong association with infant and child survival. Years of education ranges from 0 to 19, with quartiles at 4, 7, and 8. The fitted quadratic shows no effect of a few years of education, but a steady and large decline in risk after that. Around the median, each year of education is associated with a 7% decline in risk at any given age, after adjusting for other characteristics. We find no significant differences in survival by residence, with a point estimate of 4% higher risk in the urban sample. The erosion of the traditional survival advantage of urban areas could be associated with higher prevalence of AIDS in the cities.

Table 3 Parameter estimates for infant and child mortality in Kenya

Variable	*Term*	*Coefficient*	*Standard error*	*Hazard ratio*

Family	σ_2	0.613	0.086	1.846
Community	σ_3	0.680	0.055	1.973

Random Effects

The most remarkable feature of these results, however, is the large amount of residual variation found at the family and community levels, with estimated standard deviations of 0.613 at the family level and 0.680 at the community level. Just like we did with logit models, we can interpret the standard deviations in essentially the same way as other coefficients, exponentiating them to obtain hazard ratios. To see this point write the family random effect as $a_{jk} = \sigma_2 z_{jk}$, where $z_{jk} \sim N(0, 1)$ is a standard normal random effect, and note that children who live in families with frailty that is one standard deviation above the mean have a log-hazard 0.613 higher than comparable children in the average family. This translates to 85% higher risk, everything else being equal. In the same fashion, we can write the community random effect as $a_k = \sigma_3 z_k$, where z_k is a standard normal random effect, so children who live in a community with frailty that is one standard deviation above the mean have a log-hazard of 0.680, higher than comparable children in the average community. This translates to 97% higher risk.

It is interesting to compare the magnitude of the observed and unobserved effects on infant and child mortality. One way to do this is to combine all the observed risk factors other than age of the child into a single measure of risk, effectively multiplying the terms representing urban residence, mother's education, sex, cohort, age of mother at birth of the child, birth order, and length of previous birth interval, by their coefficients. Using this summary measure, we find that children in the third quartile of relative risk have 61% higher risk than those in the first quartile. In contrast, the results reported for the family and community effects translate into 2.3- and 2.5-fold increases in risk across the interquartile range, respectively. More broadly, the range from the first to the 99th percentile in observed risk factors translates to an eight fold

Figure 2 Log risk by mother's age, birth interval, and education.

increase in risk, whereas the equivalent ranges in family and community frailty translate into 17- and 24-fold increases. Clearly, there are very substantial risks associated with family and community characteristics that remain unobserved.

Conditional and Marginal Probabilities

With hazard models it is often useful to convert the results into more familiar survival probabilities. With multilevel survival models we have a choice between conditional and marginal probabilities, which lead again to subject-specific and population-average interpretations of the results.

Consider conditional probabilities first. These are often calculated by setting covariates to their means, but here we will set both the observed and unobserved effects to the first and third quartiles of their distributions. The calculation is based on the fact that in a proportional hazards model the survival function is given by

$$S(t|x_{ijk}, a_{jk}, a_k) = \exp\{-\Lambda_0(t)\exp\{x'_{ijk}\beta + a_{jk} + a_k\}\}$$

We accumulate the estimated baseline hazard up to ages one and five, set the observed relative risk $x_{ijk}\beta$ to the estimated quartiles (which are 0.15 and 0.63), and set the family and community frailties to the estimated normal quartiles $\pm 0.674\sigma_2$ and $\pm 0.674\sigma_3$. Figure 3 shows the results. The conditional probabilities of infant death range from 14 to 119 per 1000, and the probabilities of child death from 22 to 183, with differences by community and family frailty exceeding differences by observed risk. The probabilities of infant death for the first and third quartile of observed risk are 14 and 22 if the family and community are in the first quartile of frailty, but 75 and 119 if they are both in the third quartile of frailty.

We can also calculate marginal or population average probabilities of infant and child death at any given values of the observed covariates by integrating over the family and community frailties

$$S(t|x) = \iint S(t|x_{ijk}, a_{jk}, a_k)\, da_{jk}\, da_k$$

Figure 3 Probability of infant and child death by quartiles of frailty and observed risk.

Evaluation of the integral must be done using numerical integration routines; in this analysis we used 12-point Gauss–Hermite quadrature. We find average probabilities of infant death of 47 and 74 per 1000 for children at the first- and third-risk quartiles, respectively, when averaged across all families and communities. The corresponding probabilities of child death are 74 and 113 per 1000.

Intraclass Correlations

The variance parameters in random intercept models have a direct interpretation in terms of intraclass correlation. In the context of survival models, Oakes (1982) has shown that the variance parameter in two-level models with gamma-distributed frailty is closely related to Kendall's τ, a measure of ordinal association. These results have not been generalized to other settings, and our frailty distribution is in fact log normal, but we can always calculate probabilities of surviving to age one and five based on the results given above, and use these to estimate standard measures of correlation. These probabilities, and hence the derived measures of correlation, depend on the observed covariates. For these data, the Pearson correlations are very low at the lower end of the distribution of risk, but they increase very rapidly at the high end, with the intrafamily correlation reaching as high as 0.18 for infant and 0.21 for child mortality. Even among children of different families in the same community, the intraclass correlation climbs up to 0.10 at high-risk levels. For further details, please see the full analysis in Rodríguez (2008).

Bibliographic Remarks

Not surprisingly multilevel survival models have found many applications in demography. Guo (1993) uses sibling data in a two-level model to estimate child survival in Guatemala. Sastry (1997) uses a three-level model to look at individual, household, and community effects on child survival in Brazil. Steele et al. (1996) study duration of contraceptive use in China using a multinomial version of a discrete hazards model to handle competing risks. Barber et al. (2000) use a discrete-time three-level model to study the initiation of permanent contraceptive use in Nepal. Lillard (1993) was a pioneer in considering joint modeling of marriage and fertility. Following in this tradition, Steele et al. (2006) use multilevel/multiprocess models to study cohabitation and childbearing among young British women, allowing for endogeneity of fertility decisions. Pamuk et al. (2011) use multilevel logistic regression to study the likelihood of infant death using a three-level logit model with random intercepts at the community and country levels.

Multilingual Language Development

Alejandro E Brice, University of South Florida St. Petersburg, St. Petersburg, FL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Typical language development has far too long been predicated on monolingual development. It is estimated that approximately more than half of the world's population speaks more than one language. Multilingual or multilanguage acquisition differs from monolingual development. It involves more layers that affect ultimate acquisition including second and/or multiple language acquisition factors, environmental factors, individual factors, developmental factors, and, if the child has disabilities, then disabilities are also confounding factors. In addition, the following factors influencing multilingual language acquisition will be discussed: (1) second and/or multiple language acquisition; (2) language dominance and proficiency; (3) language maintenance; (4) language model; (5) language deceleration; (6) cross-linguistic influence, that is, language transference; (7) cross-linguistic influence, that is, language interference; (8) cross-linguistic influence, that is, code switching and code mixing; (9) ultimate attainment; (10) language loss (attrition); (11) language fossilization; (12) environmental factors; (13) individual and developmental factors; (14) biological, neurological aspects of multilingualism; (15) disability factors; and (16) strategies for promoting multilingualism. This article will briefly present these overlaying components and provide suggestions for language professionals in promoting multilingualism.

Introduction

The notion of typical language development has far too long been predicated on monolingual development. It is estimated that approximately more than half of the world's population speaks more than one language (Grosjean, 2010). Multilingualism is the norm worldwide. Thus, the monolingual view to language development is inadequate to describe language acquisition from a global perspective. In addition, the viewpoint that multilingual language development mirrors monolingual language when only one of the child's languages is considered is also a misguided assertion (Brice and Brice, 2009; Grosjean, 1989).

Multilingual or multilanguage acquisition differs from monolingual development (Brice and Brice, 2009). It involves more layers that affect ultimate acquisition including: (1) second and/or multiple language acquisition factors, (2) environmental factors, (3) individual factors, (4) developmental factors, and (5) if the child has disabilities, then disabilities are also confounding factors. This article will briefly present these overlaying components and provide suggestions for language professionals in promoting multilingualism. See **Figure 1**.

Second and/or Multiple Language Acquisition

Learning a second language (L2) or multiple languages is not a straightforward additive process to English. It does not involve a simple one-to-one correspondence. Grosjean (1989) wrote that a bilingual speaker does not consist of two monolinguals speakers. Rather a bilingual speaker is an individual who has access to two languages that interact with each other constantly, even when one language is the primary mode being activated (Grosjean, 1989). When young children acquire two languages simultaneously from birth, their first language (L1) is bilingualism. Their two languages interact in positive and sometimes negative ways from the very first day they are exposed to the two languages (i.e., language transference and interference). Research has indicated that young multilingual children can appropriately code switch as early as 18 months of age when spoken to in L1 or L2 (Brice and Wertheim, 2004/2005; Döpke, 1992; Pearson and Fernandez, 1994; Pearson et al., 1997; Pearson et al., 1995; Wapole, 2000). Hence, no language confusion appears to be occurring for typically developing children.

Learning a third language (L3) differs from learning an L2 (Jessner, 2006). Third language acquisition (TLA) requires different skills than those used by bilingual (L2) learners. Jessner (2006) stated that TLA should be the basis for studying bilingual and monolingual language acquisition, and not vice versa. Cenoz (2000) illustrated that TLA differs from second language acquisition (SLA) in terms of how the languages may be acquired. In SLA, the L2 may be acquired simultaneously with L1, or sequentially with L1, whereas in

Figure 1 Interaction of bilingual factors.

TLA, four different conditions exist: (1) L1, L2, and L3 may be acquired simultaneously; (2) L1, L2, and L3 may be acquired sequentially; (3) L2 and L3 are acquired after L1; and (4) L1 and L2 are acquired before L3. In addition, the acquisition process of any of the languages may be halted by the process of acquiring any of the other two languages. The interruption process may apply to L1, L2, or L3 at any point in time; consequently, the TLA becomes more complex than either L1 or L2 acquisition. Due to the possible interruption of learning, individuals may also later relearn any of their interrupted languages. Chronological acquisition of L1–L3 does not necessarily equate with proficiency in any of the languages (Hufeisen, 1997). However, Jessner (2006) stated that in TLA, related languages tend to transfer learning more than unrelated languages. Consequently, cross-linguistic influences (CLIs) in TLA are more complex than in SLA.

Language Dominance and Proficiency

The concepts of language proficiency and language dominance are notions that seem to imply that one should consider each language separately instead of in a combined fashion. Hence, proficiency should be investigated in terms of communicative competence (Canale and Swain, 1980; Cazden et al., 1972) and proficiency utilizing a combined approach as is seen in vocabulary studies where total vocabulary and total conceptual vocabulary measures are obtained (Pearson and Pearson, 2004). Dominance varies across speech and language domains (phonetics, phonology, morphology, semantics, pragmatics, etc.) and also seems to vary within each speech domain. Flege and Eefting (1987) demonstrated that multilingual speakers are capable of creating different phonetic categories for voiceless stops across languages. Grosjean's (2001) notions of language modes fits this paradigm. Language modes refer to what extent L1 and L2 are activated and to the continuum of activation among the languages. Bullock et al. (2006) summarize this by stating, "Such research contends that bilinguals' language use is malleable in that they may behave differently according to which language they are producing or perceiving at a given time" (p. 9). Hence, dominance in a multilingual child is not an overall ability assigned to L1, L2, or L3 but one that seems to vary according to language, language domain, and task.

Language Maintenance

> My husband and I adopted twin sons a little over 2 years ago. They were 8 months old when we brought them home from their native country Cambodia, where the only language they had been exposed to was Khmer. My husband and I are both Hispanic in culture, language and heritage. Even though we live in the *Southern USA* [name changed] we speak Spanish at home and with our Hispanic friends as well as, of course, family. We have always wanted to raise our children to be multilingual since that has been both of our experiences. We know that the speech delay they have is very understandable given that they are boys, twins and have been exposed to several languages. A number of English-speaking friends and professionals have, suggested changing to English only at home.

> A few mothers of bilingual children have formed a website and we exchange information we learn out in the 'real world' of raising our own bilingual children. The question is, a few 'professionals', have asked that some parents stop the second language at home to develop the English or whatever the community language is. What is the standard advice? Why do we get this question so often? This really goes against our instincts to not speak our own language to our children.

The above solicitations for advice came from two mothers of multilingual children. The first mother was raising two boys with some speech and motor delays, while the second mother was raising her typically developing multilingual child. Yet, the essential question that they asked was the same, i.e., can we speak the native language at home and raise our children in a multilingual environment? It also appears that they have been given uninformed advice to speak only the outside language at home (English in the first case as this came from the United States and French in the second case as this came from a parent in France). What does the research say and what are the logical consequences of speaking the native language in the home versus speaking the outside language (e.g., English) in the home environment? Research has documented that multilingualism has cognitive and linguistic advantages (Bialystok, 2007; Hakuta, 1986). Research with multilingual children with disabilities has also shown that multilingualism does not have any detrimental effect on language development even with children who have prominent language disabilities as seen in Down syndrome (Kay-Raining Bird et al., 2005). Kay-Raining Bird et al. stated that,

> There was no evidence of a detrimental effect of bilingualism. That is, the bilingual children with DS scored at least as well on all English tests as their monolingual DS counterparts. Nonetheless, there was considerable diversity in the second- language abilities demonstrated by these individuals with DS. (p. 187)

Kohnert (2008) stated that in multilingual homes there exists "… the availability of rich language in the environment and diverse opportunities to develop and use a particular language for meaningful communicative interactions" (p. 10). Thus, maintaining the native language allows parents to communicate with their children in perhaps the best language medium available to them, i.e., their own native language. In addition, speaking in the other language (e.g., English) may diminish communication and possibly provide a less-than-rich experience and inadequate language model. It will take a child between 5 and 6 years to acquire nativelike classroom language abilities in English (Thomas and Collier, 1997). Speaking only English at home will not accelerate English learning and may in fact delay English acquisition due to a less rich language input. Therefore, why do professionals advocate such advice when it is not supported by the research and may go against the parent's instincts? It may be ignorance. For example, according to popular misconception it is believed that when two individuals are speaking in another language they are talking about you. As language specialists,

we must take a broader view (i.e., bilingual or multilingual view) to language use and development. It is our belief that multilingualism is a positive attribute and should be encouraged with all individuals (especially, those with language and learning disabilities). In sum, all aspects of multilingualism need to be understood.

Language Mode

The multilingual speaker has access to both their interacting languages at all times. Hence, the multilingual speaker never truly shuts one language off even when speaking in monolingual fashion. A multilingual speaker has access to two phonologies, two lexicons, two syntactic systems, and two pragmatic manners of interaction. They can choose which system may best convey their message. A more appropriate means of classifying a multilingual speaker's language abilities is to think of neither their L1 nor their L2 abilities but rather, to think of their abilities as a third combined language form that occurs at all times. The combined form is a continual interaction and combination of L1 and L2. The combined form cannot be subtracted from L1 or L2. Sometimes, the combined form involves code switching, or code mixing. At other times, the combined form occurs even when in monolingual mode. When the multilingual speaker is speaking solely L2 (e.g., English) or L1 (e.g., Spanish), their brain is always in the combined mode (i.e., multilingual).

The implication for language professionals is that any assessment of a multilingual child's learning and/or language abilities should include their combined dual language abilities. If the language professional is fortunate to have results from both languages, then these results must not be looked at separately. Assessment and test results should be investigated as combined L1 and L2 efforts (i.e., combined mode). The language specialist should look at both languages and their combined receptive and expressive language abilities in oral and written language, phonology, morphology, semantics, syntax, and semantics. Poplack (1980) postulated that a multilingual speaker has to abide by both languages and their grammar rules when code switching and code mixing. We will postulate that even when the multilingual speaker is communicating in solely one language, he or she is keeping track of both language grammars simultaneously. An example of this is seen in momentary language interference when a multilingual speaker attempts to read an English word as a Spanish word, or when a multilingual speaker displays a broader definition of vocabulary in one language because they have accessed the vocabulary meaning in both languages (e.g., 'father' in English, 'padre' in Spanish, 'padrastro' or stepfather in Spanish; hence, 'father' can also encompass a broader meaning to include 'stepfather').

Consequently, the term 'multilingual' does not accurately reflect the complexity of the language system of the child who has multilingualism as L1. Multilingualism is not simply the use of two languages, but rather, use of three language modes (L1, L2, and their combined languages). A multilingual individual always operates in some varying degree of combined mode because L1 and L2 cannot be completely deactivated or separated. See Figure 2.

languages, negative consisting of interference among the languages, or simply interaction of the languages (such as code switching or code mixing) (Jessner, 2006). Language transference benefit occurs when bilingual speakers are able to attain a high level of proficiency in both languages (Cummins, 1984). Regarding L3 learners, high levels of proficiency would need to be obtained among two of their three languages (e.g., L1–L2, L1–L3, or L2–L3). It is also conceivable that transference would occur among all languages if high levels of proficiency were obtained in all languages.

Phonetically speaking, Flege et al. (2003) have shown that the phonetic systems of bilinguals interact. Age of arrival to the country (e.g., early vs late) and amount of L1 use determined the extent to which speech production of English was influenced (vowels in this study). With regard to vocabulary, research by Pearson and Pearson (2004) recommend the use of Total Conceptual Vocabulary so that students will not be identified as having small vocabularies. Therefore, multilingual vocabulary should only be considered when both languages are measured jointly. Montrul (2006) documented that Spanish-English-speaking adults were capable of achieving balanced syntactic abilities in both of their languages. These results indicate that the adults showed robust knowledge of both L1 and L2 syntactic structures, something that would not have been possible if the languages were separate and did not interact. Hence, positive transference seemed to have occurred at the syntactic level.

The question then arises not if dominance and proficiency are suitable theoretical constructs appropriate for multilingual students, but do the bilingual speakers catch up or attain ultimate proficiency in both of their languages?

CLI: Language Interference

Children can and do 'fall between the cracks.' Language interference, language loss, and fossilization can and do occur with SLA. Language interference is the negative influence that a language may have on subsequent languages. It is the imposition of one language onto another. An example is where the Spanish speaker may pronounce a 'th' as a 'd' sound. This is because the 'th' sound does not occur in Spanish of the Americas (excluding Castilian Spanish from Spain). The multilingual speaker will utilize a close approximation from their native language (L1). This interference is normal and will typically disappear given time, adequate English exposure, and perhaps instruction (Cummins, 1984). Language loss is when one of the two languages (typically, the native language) diminishes in growth or disappears. Some of our research with multilingual elementary-aged students (third-, fourth-, and fifth-grade students) indicates that this occurs with typically developing students (i.e., no disabilities present) (Brice et al., submitted). Language loss has been well documented by others (Selinker, 1991). Please note that multilingual children can also shift toward greater English vocabulary with increased English exposure (Kohnert and Bates, 2002; Kohnert et al., 1999).

Brice and Montgomery (1996) showed that language-impaired students and English language learners (ELLs) may display pragmatic problems in the classroom, albeit due to different causes. The ELL students demonstrated pragmatic communicative competence and were in the initial stages of acquiring English. Consequently, the Spanish-English-speaking students were accessing both their Spanish linguistic and pragmatic skills in order to accomplish pragmatic proficiency, yet had not established typically developing levels of monolingual children. Some pragmatic interference errors were noted for the ELL students.

CLI: Code Switching and Code Mixing

Code switching and code mixing are two forms of language alternation exhibited in multilingual speakers' language. It is a typical occurrence and does not signal language difficulties (Brice and Brice, 2009; Grosjean, 2010). Code switching is when the alternation occurs across sentence boundaries (intersentential alternations) as in the sentence, "I'm going to read the directions. Prestes atención? (pay attention)." The switch occurs between the English and Spanish sentences. Code mixing occurs within a sentence (intrasentential alterations). It is developmentally and linguistically more complex of a behavior (Brice and Brice, 2009). An example is when the teacher says, "Open your books to pagina diez (page ten)." Code switching and code mixing behaviors are exhibited along a continuum of language proficiency abilities, i.e., individuals may exhibit low-level language alternation behaviors, midlevel alternation behaviors, or high-level language alternation behaviors.

Poplack (1980) says that a multilingual speaker when code switching/mixing, has to abide by the language rules of all languages. Hence, code switching and code mixing are rule-governed behaviors. A third form of language alternation is the use of loan or borrowed words from another language. However, with loan/borrowed words, one does have to be multilingual as the borrowed word becomes completely incorporated into the guest language (e.g., "I took karate lessons at the dojo").

Ultimate Attainment

Bialystok et al. (2010) stated that:

> Bilingual children need to distribute their language-learning time across two languages and it is likely that some words occur in a context in which they only use one of their languages. In this sense, there is little reason to think that bilingual children are compromised in their expressive ability and every possibility that their **combined vocabulary is equivalent to or greater than the vocabulary of monolingual children** [emphasis added]. (p. 525)

Lugo-Neris et al. (2010) found that children with greater language proficiency in one of their two languages made the most gains from vocabulary intervention. Students with low-level aptitudes in both their languages did not show equal gains as students with better Spanish proficiency. Consequently, ultimate attainment abilities may depend on robust L1 skills. Bialystok et al. (2010) determined that

multilingual students are not hindered in school and academic language and attained ultimate vocabulary attainments for school words. In sum, it appears that ultimate vocabulary attainment is possible given a strong L1, sufficient exposure and adequate vocabulary use, and sufficient time acquiring their two languages (Bialystok et al., 2010; Gathercole, 2010; Lugo-Neris et al., 2010).

Pham and Kohnert (2013) found that bilingual children's English skills overtook their Vietnamese receptive and expressive vocabulary skills at approximately 9 and $7^1/_2$ years of age, respectively. While both languages increased in vocabulary, English became the more dominant language. Expressive skills lagged receptive English proficiency levels. This would indicate that ultimate attainment can be achieved in English; however, this may come at a risk of lesser native language skills (especially if the native language is not fully developed).

Research investigating speech perception abilities of multilingual adults indicates that some bilinguals are capable of attaining equal or ultimate attainment abilities in their L2 (Brice and Brice, 2008). However, this ability was found among only middle bilinguals (i.e., sequential bilinguals who had begin their English acquisition between 9 and 15 years of age and also been exposed to advanced English levels for at least 6 years). It should be noted that most bilinguals achieve, at minimum, functional abilities in both languages. Consequently, it appears that adequate exposure and maintenance to both languages is requisite for L2 development.

Language Loss (Attrition)

Under ideal conditions (e.g., near equal amounts of both languages such as 60% English and 40% Spanish) balanced multilingualism can result (Brice and Wertheim, 2004/2005; Pearson et al., 1997, 1993, 1995). However, language attrition typically occurs under less-than-perfect multilingual conditions (Anderson, 1999; Seliger and Vago, 1991). Given that English is the predominant language in schools, in the media, and for students, it serves as the primary means of communication with teachers and most friends; it seems very plausible that English becomes dominant and that Spanish becomes targeted as a minority language. Consequently, the home language will develop minority status and be at risk for language loss. The acquisition of English while losing the home language has dramatic language learning and educational consequences: (1) the child's language development stalls and resembles a language learning disability, (2) communication with both parents may weaken, (3) it takes a significantly longer time to fully develop English academic language skills (Thomas and Collier, 1997), and (4) positive transference of language skills from L1 to L2 may be lessened (Cummins, 1984, 1998).

Cummins (1984, 1998) stated the existence of a threshold hypothesis whereupon the student must achieve certain proficiency levels in their L1 before language transfer occurs and before the cognitive benefits of balanced multilingualism can be attained. If this threshold is not attained then what may result is language loss (or subtractive multilingualism).

Language loss among typically developing multilingual students may be more common than many educators may suspect. It is to the benefit of the child and the school that multilingual, English learners maintain their home language (i.e., less referrals for speech–language special education interventions as these students may appear to be language learning disabled). Research has demonstrated that promoting multilingualism promotes English language development and acquisition (Brice and Wertheim, 2004/2005; Döpke, 1992; Pearson and Fernandez, 1994; Pearson et al., 1997, 1995; Wapole, 2000). Brice et al. (2006) offered some suggestions in educating ELLs. Some specific language recommendations include: (1) modelling correct English language, (2) providing grammar drills with direct instruction, and (3) allowing for code switching to occur. In conclusion, language professionals should promote multilingualism and encourage teachers, family members, and students to be proud of their native language and to use it often.

Language Fossilization

Language fossilization is where growth in English (or the L2) languishes or stops short (Selinker, 1972). Both language loss and fossilization are real possibilities for multilingual children. Acquiring English and maintaining the native language are not automatic guarantees for multilingual children. Selinker (1972) first defined the concept of fossilization as an end state (final stage) and steady state (continuous stage) of language abilities that are characterized by stagnated growth in L2 development. Selinker (1991) refers to all stages of growth between two languages (until ultimate attainment is achieved) as interlanguage (IL) or intermediate stages of L2 learning. Therefore, fossilization is a permanent cessation of IL learning. Han (2004) identifies several possible causal factors for fossilization: (1) lack of instruction, (2) lack of language input, and (3) satisfactory communicative abilities.

Environmental Factors

According to Wong-Fillmore (1992), multilingualism (i.e., high levels of proficiency and balanced abilities) is possible only when certain conditions are met:

1. *Need to communicate.* The child and others must fulfill communicative intents. Motivation and desire to communicate are integral aspects. Language professionals must provide opportunities for real communication.
2. *Access to language from speakers of that language.* Multilingual individuals must have access to English and this English must be of a high level.
3. *Interaction, support, and feedback from speakers of that language must be present.* This interaction and feedback must be adequate for the learning to occur.
4. *Time.* It takes considerable time to adequately learn an L2, especially beyond just conversational abilities (Cummins, 1984; Thomas and Collier, 2002). It may take from 4 to 6 years or 5 to 7 years to acquire nativelike abilities for classroom language. Thomas and Collier state that this occurs only if the child has a strong base in their L1; otherwise, it may take up to 10–13 years. Again, support of the native language is crucial for English development.

Individual and Developmental Factors

The child's cognitive aptitude and also stages in their language, cognitive, and physical development play roles in L2 learning. It is apparent that gifted and talented students may experience accelerated learning in acquiring English (Brice et al., 2008). Just as developmental stages affect L1 development, these processes and stages also affect SLA. It is beyond the scope of this article to detail all these processes. However, it must be mentioned that the interaction of developmental stages among two developing language systems is more complex and varied than with monolingual development.

In sum, Kohnert (2013) states that bilingual/multilingual students must have the means, opportunities, and motivation to acquire their languages and develop proficiency and proficiency may vary in each of the languages.

Biological and Neurological Aspects of Multilingualism

Language and cognition are multiphasic processes (i.e., language and thinking develop in different stages in brain development) (Sakai, 2005; Uylings, 2006). Most brain growth occurs after birth, i.e., postnatally (Eliot, 2001). Evidence indicates that various aspects of brain development occur into late adolescence and/or early adulthood: (1) white matter increases from 4 to 21 years of age (Guidd, 2004); (2) myelin growth continues into adulthood (Uylings, 2006); (3) synaptogenesis (i.e., creation of new synapses) reaches maturation around 10–15 years of age (Uylings, 2006); (4) neurotransmitters such as dopamine, noradrenaline, and serotonin reach maturation around adolescence or early adulthood, (5) acetylcholinesterase (a key enzyme in the nervous system) matures around 18 years of age or later (Uylings, 2006); and (6) neuron dendrites and synapses and brain neurotransmitters are not expected to reach full development until adolescence or later (Uylings, 2006). Consequently, it appears that many developing brain capabilities occur in late adolescence or early adulthood, which would favor a sensitive and noncritical period to cognition and learning language (meaning that language learning neither reaches a plateau nor ceases around puberty). Neurologically, it appears that L2 learning can occur in adulthood (Grosjean, 2010).

Disability Factors

The most perplexing question among monolingual language professionals is whether bilingual or multilingual children with disabilities can acquire all languages, i.e., near-nativelike abilities. Clinical experiences and research support the notion that these children are fully capable of language and cognitive growth in their two language systems (Brice and Brice, 2009; Kohnert, 2008). The limiting factor appears to be the extent of their disability and not their two languages.

Several studies investigating typically developing monolingual children, typically developing bilingual children, monolingual children with disabilities, and bilingual children with disabilities have demonstrated similar patterns (Brice and Brice, 2009; Windsor et al., 2010). Brice and Brice (2009) found that when comparing phonemic awareness and phonics skills among kindergarten students a descending order of correctness emerged among the following groups: (1) monolingual typically developing students, (2) bilingual typically developing students, (3) monolingual students with disabilities, and (4) bilingual students with disabilities. This order of abilities was also found when comparing receptive syntax and directions for 8-year-olds: (1) English only, (2) bilingual, (3) English only – primary language impairment, and (4) bilingual – primary language impairment.

Strategies for Promoting Multilingualism

Research supports the notion that multilingualism may be an advantage (Hakuta and Bialystok, 1994). Consequently, the following points are for making learning multiple languages an additive process:

1. Language specialists should make learning English in the classroom and in social environments a positive experience in which both languages are valued. High-level language and thinking should be involved. Multilingual children should be encouraged to participate in verbal and literacy problem-solving tasks. Speech-language pathologists (SLPs) should verbalize how they solve problems to provide a cognitive model.
2. Multilingualism should be promoted both at home and in the school. Children should be allowed to speak either Spanish or English when it facilitates their communication (Brice and Perkins, 1997). The children's comfort level for using English should be allowed to mature and not be a forced issue.
3. Children should have well-developed Spanish skills before learning English (Wong-Fillmore, 1992).
4. Opportunities for reading and writing in both Spanish and English should be provided. Parents should be encouraged to read to their children in Spanish. Emergent literacy skills, knowing about the written word and books, are generalizable across languages. Appreciation of books is not language specific.
5. Ample opportunities to interact with native Spanish speakers should be provided to maintain L1.
6. The children should receive appropriate instruction in English. Learning English should reflect natural language usage.
7. Children should be allowed to make errors in English as this is a natural phenomena.

Conclusion

Working with second and multiple language learners with and without disabilities provide extra challenges for language professionals. Some of these challenges are unique, yet, neither teaching nor therapy has been an easy task. Consequently, we must provide high-quality services to all our students, clients, and/or patients. It is in our nature as language professionals to overcome language barriers be it a result of multilingualism, disability, or both.

Abstract

Interest in the phenomenon of multilingualism has considerably grown over the last few decades. Since the discovery of cognitive advantages of bilingual children over their monolingual peers in the 1960s positive attitudes have been developed toward the phenomenon, mainly in Applied Linguistics. The field of multilingualism has been studied from both the social and the individual perspective. Current work on multilingualism has focused on the dynamics and complexity of multilingual development and use. The use of English as a *lingua franca* or third language as part of current individual multilingualism will also be addressed.

Introduction

Scholarly interest in multilingualism can be described as a fairly new development in comparison to the phenomenon which has existed for a much longer time in human history. Until rather recently, bi- and multilingual speakers were often treated as schizophrenic and cognitively handicapped speakers with deficits in each of their languages. Ever since Peal and Lambert in the 1960s discovered the cognitive advantages of bilingual children over their monolingual peers the attitudes toward bi- and multilingualism have changed and lately Bialystok's seminal work on cognitive advantages in bilinguals over the life span has definitely shaped our knowledge on emergent cognitive properties in multilingual individuals. Due to the trained flexibility in the bilingual brain she and her collaborators attested elderly bilinguals to be protected against the onset of dementia (for an overview see Bialystok, 2009).

The discussion of the topic of competence in more than one language is complex because multilingualism can be encountered as a societal, discursive, and individual phenomenon. The overview provided in this article can only alert the reader to relevant fields of research. Matters of definition and terminology are dealt with first. Second, problems of assessment of multilingual proficiency are addressed. Third, an overview of linguistic, social, and psycholinguistic aspects of multilingualism is given. Fourth, multilingualism and multilingual development as complex and diverse phenomena are discussed. Finally, a brief outlook into challenges in multilingualism (research) is provided.

Definitions and Terminology

The term multilingualism has been used with increased frequency over the last few years. Yet, a critical analysis of these publications reveals that this term is used to cover a range of meanings, some of which appear to be contradictory. Many still use the term multilingualism to refer to any system with more than one language. As bilingualism is the most commonly studied form of multilingualism, the two terms are also used synonymously. In contrast, an increasing number of researchers argue that bilingualism should be seen as a subtype of multilingualism. Within the same group, third language acquisition (TLA) is not discussed as extended second language acquisition (SLA), but rather as a different language learning process in various respects (cf Jessner, 2008a).

As pointed out by Kemp (2009), the variety of terms and their origins derive from (1) the complex nature of use of various languages in a multilingual context and (2) the researchers' backgrounds, ideologies, and purposes. So whereas from a psycholinguistic perspective bi- and multilingualism, SLA, and TLA are the most common terms in use, scholars with other theoretical backgrounds have recently introduced different terms to describe the use of multiple languages such as polylingualism (Jorgensen et al., 2011), metrolingualism (Otsuji and Pennycook, 2010), or heteroglossia (Bakhtin), to name but a few. In European Union language policy, mainly in educational-oriented research, the term plurilingualism has been established to denote individual multilingualism in contrast to multilingualism on a social level. From an international perspective, multilingualism is the term most prominently used.

With the increase in interest in the field of multilingualism, several problematic issues, in particular with regard to terminology, have arisen. For instance, whereas in traditional SLA research the terms L1 and L2 are clearly defined, research on life span development in multilingual individuals shows that the chronological order in which languages were learnt is not necessarily the most useful factor in defining the L1, in the sense of 'dominant language,' of a multilingual person. An L1 might become an L2 or L3 at a later phase in a multilingual person's life due to a change of linguistic needs. The use of a 'primary/secondary' language system in order to deal with changes in language dominance in a bilingual system has also been suggested (Herdina and Jessner, 2002). Primary learner multilingualism refers to a third language learnt after primary bilingualism, whereas secondary learner multilingualism refers to the acquisition of two languages simultaneously after the primary language system has been acquired (see also Hammarberg, 2010 on the chronological approach to the terms L1, L2, L3, etc.). The strong role that emotion can play in multilingualism might also lead to further complications in terms of individual classification (Pavlenko, 2005). L1 might also denote the language of the heart, e.g., the language somebody shares with her/his partner regardless of the level of proficiency in that language and/or the frequency

of use. Not to mention the problematic defining dimensions of high degrees of proficiency, functionality, identification, and automaticity in the case of the native language(s), as pointed out by Skuttnab-Kangas (1984).

Assessment of Multilingual Proficiency

Guiseppe Mezzofanti, who lived in the nineteenth century, was not only reported to have been fluent in 60 languages, but also to have had translating ability in twice this number. Another linguist living in the same century was Emil Krebs, a German Sinologue who became famous for being literate in 68 languages and capable of dealing with another 111 languages. Ziad Fazah, a born Lebanese, who has acquired most of his languages autonomously, is fluent in 58 languages such as Chinese, Thai, Greek, Indonesian, Hindi, and Farsi. A number of bilingual writers such as the Polish immigrant Joseph Conrad have succeeded in the development of excellent writing abilities in a language they acquired later in life. Elias Canetti whose L1 was Sephardic (Spanish Hebrew) won the Nobel Prize in literature for a book written in German which was actually his fourth language. One of the most well-known actresses Audrey Hepburn was fluent in Dutch, English, French, Italian, and Spanish. She came from a bilingual family and traveled between and lived in a number of countries. Many scholars working in philology claim full competence in several – in many cases typologically related – languages. But how are all these abilities related? What if a person can say 'good morning' in a number of languages? Is s/he multilingual? Is a German-speaking student studying English at university level a bilingual? Can a nonliterate person who is fluent in three languages be called a multilingual? Can a person achieve full mastery of any language if he/she learnt the languages as an adult?

Typologies of bilingualism focusing on competence have taken either a minimalist or maximalist approach. Bloomfield (1933) defined bilingualism as nativelike control of two or more languages, whereas Macnamara (1967) characterizes a bilingual as someone who possesses some proficiency in any one of the four language skills in a language other than his/her mother tongue. Years later Li Wei (2000) came up with 36 types of bilingualism including rarely used categories such as diagonal bilingual for a person "who is bilingual in a nonstandard language or a dialect and an unrelated standard language." Whereas dichotomies are widely used both in bi- and multilingualism as they present clear ways of classification, Valdes (2005) argues for a continuum of bilingual proficiency, ranging from full monolingual proficiency in language A to monolingual proficiency in language B by taking different levels of proficiency into consideration. The conceptualization of a continuum for proficiency in three and more languages still awaits realization.

What has become clear today is that a discussion of balanced, nativelike proficiency in all of a multilingual's languages has been banned. Instead holistic concepts of bilingualism stemming from Grosjean and Cook who portray the bilingual speaker/user as competent but different from a monolingual have turned out to be influential in the development of the field of bi- and multilingualism. According to a holistic or realistic perspective the bilingual person is a competent but special speaker/hearer (Grosjean, 2010) who in contrast to a monolingual person develops different skills, as taken up later by Cook (e.g., 2003) in his construct of multicompetence. They both have argued for the nonapplicability of monolingual norms in multilinguals and consequently in research on bi- and multilingualism.

Codeswitching, Transfer, and Translanguaging

In a multilingual repertoire language systems do not coexist without influencing each other. Weinreich (1953) initiated research on languages in contact. Since then a number of crosslinguistic phenomena have been identified, depending on the fields of research. For a long time SLA research concentrated on interference and transfer, whereas bilingualism research focused on codeswitching and borrowing phenomena. In 1986 Kellerman and Sharwood Smith introduced crosslinguistic influence to cover phenomena studied in both fields.

Research on TLA necessarily has to go beyond the study of two languages in contact. Over the last 15 years research on TLA or multilingualism has been increasingly intensified with the main goal of describing multilingual phenomena in order to investigate differences and similarities between second and third language acquisition (see, e.g., Cenoz et al., 2001, 2003; De Angelis, 2007; Aronin and Hufeisen, 2009). In a multilingual system transfer phenomena not only take place from the L1 to the L2 and vice versa but have also been evidenced from the L1 to the L3 and from the L2 to the L3 and vice versa. Combined crosslinguistic influence occurs "when two or more languages interact with one another and concur in influencing the target language, or when one language influences another, and the already influenced language in turn influences another language in the process of being acquired" (De Angelis, 2007, p. 21). This expansion of transfer possibilities already shows that multilingual acquisition is a far more complex process than SLA, where the role of the L1 in the development of the L2 has been researched extensively. Some of the crosslinguistic interactions can be permanent, such as accent or fossilized use of a syntactic structure, others can be accidental or momentary (see also Grosjean, 2013).

One of the most crucial questions in psycholinguistic research on TLA is related to the status of the L2 in third language learning. In a number of studies it turned out that in L3 production the speakers did not rely on their L1 as expected, but on their L2, and in several studies of learning an L3 of Indo-European origin it could be shown that L3 learners whose L1 is typologically unrelated to the L2 and/or L3 tend to transfer knowledge from their L2 or in the case of bilinguals from the related L1 (for an overview and list of TLA studies see Jessner, 2008b). The activation of prior language knowledge is influenced by factors such as psychotypology (perceived linguistic distance between languages), recency of use, the level of proficiency in the target language, the foreign language effect, the tendency in language learners to activate an earlier second language in L3 performance, and the learner's perception of correctness of

a target word (for an overview see De Angelis and Dewaele, 2009; De Angelis et al., 2015).

Nowadays one focus in multilingualism research, mainly in educational contexts, has shifted to the phenomenon of translanguaging characterized by Li Wei (2011) as both going between different linguistic structures and systems and going beyond them and as including the full range of linguistic performances of multilingual language users. His focus is on opting between language resources, on the coordination of such resources, and on constant decision making in the multilingual individual concerning the achievement of specific communicative effects in social interaction. Garcia introduced the term in 2007 as bilingual pedagogy in order to move away from monoglossic ideologies of bilingualism, also described as flexible bilingualism by Blackledge and Creese (2010). But it should also be noted that in fact in a multilingual context, be it in an institutional or natural setting, languages do not always interact, at least not on a performance level (see also below).

Connectivity between Languages

Research on crosslinguistic phenomena as part of the multilingual mental lexicon is interested in the connectivity between the language systems involved. Although there is plenty of evidence that the languages in a multilingual system dynamically interact, there is also evidence that languages are kept apart in a communicative act. Singleton (2011) argues that "the reality of a degree of crosslinguistic conceptual permeability and transfer does not undermine the other reality of this […] essential differentiation."

Cook (2003) introduces *the language integration continuum* along which possible relationships between the languages are displayed. The continuum does not imply a direction of movement and it does not have to apply to the whole language system or affect all individuals in the same way. This also implies that the relationship between the L1 and the interlanguage within one mind is different from that between the interlanguage in one mind and the L2, when the L2 has the status of an L1 in another mind (Cook, 2006). In that sense, Cook's ideas are rather close to Grosjean's *language mode hypothesis* where he explains the factor of activation of the background languages with his concept of *speech modes*. In brief, Grosjean (2001) asserts that "at any given point in time and based on numerous psychosocial and linguistic factors, the bilingual has to decide, usually quite unconsciously, which language to use and how much of the other language is needed – from not at (*sic*) all to a lot." Thus, a speaker depending on the language mode continuum chooses a base language which is highly activated and puts the other slightly less activated languages aside. According to Grosjean (2001) a trilingual person can function in a monolingual, bilingual, or trilingual mode with various levels of activation, in relation to her or his position on the language mode continuum. Activation of the various languages is strongly influenced, amongst other factors, by the speaker(s)' usual language mixing habits, language proficiency, socioeconomic status, the presence of mono- and bilinguals, the degree of formality, etc.

Cognitive Aspects of Multilingualism

For a long time brain capacity was understood to be finite, with two implications: first, the more capacity you have the more languages you can learn and, second, if you learn something new you will be confronted with the loss of something old. Such a scientific perspective also led to the assumption that growing up with more than one language has to lead to detrimental effects on the cognitive level. Accordingly and exemplary for other academics of the time, Laurie (1890) noted the following: "If it were possible for a child to live in two languages at once equally well, so much the worse. His intellectual and spiritual growth would not thereby be doubled, but halved. Unity of mind and character would have great difficulty in asserting itself in such circumstances" (quoted after Baker, 2011).

Only when Peal and Lambert (1962) reported in their study of bilingual children in the Montreal area that the bilinguals outperformed their monolingual peers in a number of tasks, a more positive attitude toward bilingualism was created. Meanwhile it has become widely known that bi- and multilingual individuals can have tremendous advantages, not only in terms of dual language competence but also in terms of cognitive and social behavior. Hamers and Blanc (1989) argue that cognitive advantages seem to occur mainly at the level of higher creativity and reorganization of information. But with the increase in knowledge a more realistic attitude toward the phenomenon has been developed.

The work by Bialystok and her collaborators (e.g., 2009) has been very influential in the identification of differences between mono- and bilingual subjects across the life span. Many of her recent studies with a focus on executive control (processes which include attention, selection, inhibition, monitoring, and flexibility) in bilingual children and adults have attested a clear benefit to the bilingual subjects. The results of Barac and Bialystok (2012) offer strong support for the claim that bilingualism acts independently of variables such as language similarity, cultural background, and language of schooling.

Intelligence and Age

The expansion of the language repertoire, either actual or potential, is often linked to intelligence and/or age. Young learners are still considered to be advantaged while older learners are considered to have a hard time learning a new language. Such belief is obviously very closely related to the concept of a critical or rather sensitive period which attests better and faster learning in the young because of the plasticity and flexibility of the young brain up to puberty. But thanks to recent work on the interdependence between age and language learning we have learnt that (1) age cannot be studied in isolation from other variables in language learning and (2) there are no clear advantages for a certain age group (Munoz and Singleton, 2011). In fact recent research on neurological aspects of multilingualism has made it clear that although most brain growth occurs right after birth the brain develops into late adolescence and/or early and later adulthood, which would favor a sensitive and noncritical period for cognition and learning language (Uylings, 2006; see also Li, 2013).

Social Contexts of Multilingual Development and Use

In many contexts in the world more than one language is used on a daily basis. It can be assumed that multilingual individuals live in multilingual countries. But we have to distinguish between official and *de facto* multilingualism (Clyne, 1997). Although Switzerland is officially a multilingual nation most people typically grow up with one language, if in the German-speaking cantons we ignore the fact that everyone grows up with Standard German and some variety of Swiss German, an Alemannic dialect. Other examples of such countries are Luxembourg, where German and French are the official languages but Letzebuergesch is the language of daily life, or Singapore, where Standard English, Mandarin, Standard Malay, and Tamil are used for official purposes and complemented by other languages such as Singapore English, Hokkien, Cantonese, and varieties of Malay in everyday communication (Clyne, 1997). Similarly, in Malaysia, for instance, it is common that language skills are developed in various languages for the use in certain domains but that the language proficiency in those languages is rather limited (Kärchner-Ober, 2009). This phenomenon is rather common in multilingual contexts and has led to the redefinition of multilingualism as a phenomenon which views language choice and proficiency as necessarily dependent on use in specific domains of life, thereby moving away from the notion of multiple monolingualism. The fact that "[d]ifferent aspects of life often require different languages" is called 'complementarity principle' by Grosjean (2010, p. 29ff.).

The Dominant Language Constellation (DCD) is the group of the individual's most important languages that function as an entire unit and enable him/her to act in a multilingual environment in such a way as to meet all of his/her needs (Aronin and ÓLaoire, 2004). This constellation operates also on a social level, that is across communities. Examples are speakers of French in France, Canada, and Guiana, or of Russian in Israel, Austria, and Hungary. Typically a DCD includes languages of different status, depending on the context an international language, a regional *lingua franca*, one or more state languages and one or more minority (local or immigrant) languages, for instance a core multilingual repertoire in Austria includes English, German, Croatian, in Germany it includes French, German, Polish, in Hungary it is composed of English/Hungarian/German (see also Aronin and Singleton, 2012, pp. 59–75).

Functions of Languages

All the languages in a multilingual repertoire have certain functions to fulfill. Classifications of the functionality of certain languages are made according to language experience and use. For instance, early multilingualism can have different origins. Hoffmann (2001) offers the following typology by also pointing out that some language users may be placed in more than one category or that categories can overlap, or that due to mobility and other changes in a lifetime users can move from one category into another.

- Trilingual children who are brought up with two home languages which are different from the one spoken by the wider community.
- Children who grow up in a bilingual community and whose home language (either that of one or both parents) is different from the community languages.
- Third language learners, i.e., bilinguals who acquire a third language in the school context.
- Bilinguals who have become trilinguals through immigration.
- Members of trilingual communities.

Other features which could be useful for building typologies are age, acquisition process, acquisition context, and language proficiency, among others (Hoffmann, 2001, p. 19).

English as a Contact Language in Multilingual Contexts

Globalization and the resulting increased mobility has led to a worldwide spread of English. The spread of English has also been linked to its use as a *lingua franca* and as a vehicle for the spread of a culture influenced by the USA. As noted by David Graddol already in 1994 the number of nonnative users of English will correspond to half of the world's population by 2015. He is also convinced that many are scared that English, which has developed the status of a killer language, will grow, but as part of current multilingualism. In fact, nowadays in almost all cases a multilingual repertoire includes English, or in other words, multilingualism with English presents the international norm.

- English as a third language

In a number of international contexts English is not learnt as a second but as a third language. European examples are Belgium where it is learnt besides French and German, Finland where it is learnt besides Finnish and Swedish, or the Austrian province Carinthia where it is learnt besides German and Slovene. This means that in all minority language contexts English is learnt as a third language. But also immigrants whose repertoire includes two other languages very often learn English as a third language at school. An example of this phenomenon is migrant children of Turkish, Polish, Russian, or Hungarian origin in Germany or Sweden. Other contexts such as countries where English is used as a second (such as the French-speaking part of Canada) or first language in which bilingual migrants learn it as a third or even fourth language, which is also the case in the Ladin communities in South Tyrol where pupils learn English from an early age on besides Ladin, German, and Italian. In South and Central America it is the third language for many children who are heritage language speakers of Quechua, Guarani, and Mohawk.

- English as a *lingua franca* (ELF)

English is increasingly used as a *lingua franca* in politics, trade, tourism, media, and science and therefore forms part of most people's lives. In international communication situations English is chosen when the language backgrounds of the communication partners are different but they share English as a common system. This has left its traces on the development of the English language system and it has been argued that ELF should be assigned the status of a variety of its own. Although the use of ELF is as diverse as its users' competences, it has been

tried to identify structures of ELF which are common to all speakers (see, e.g., work by Seidlhofer, 2011).

Dynamics and Complexity of Multilingual Development and Use

Multilingual development is both a dynamic and complex process and nowadays scholars are realizing more and more that in the study of multilingualism, as can be seen from the above discussion, the interaction of a variety of factors needs to be taken into consideration. Individual factors in language learning such as motivation, attitudes, cognitive factors such as personality traits (See e.g., Dewaele, 2007), and also physical traits of multilingual learners (e.g., hearing capabilities) contribute to the complexity of multilingualism (research). Furthermore during the life span of a multilingual person a variety of the factors involved, such as motivation to learn one language, can be subject to change.

In order to be able to judge multilingual development and/or multilingual conversation, all variables which contribute to multilingual development and use would need to be discussed. This means that we have to be aware of the possible acquisition routes whose number increases with the number of languages learnt (Cenoz, 2000). Moreover, forms of learning are considered to play a crucial role in multilingual development. In contrast to SLA, TLA learning routes are much more diverse because very often forms of learning are of a mixed nature, that is multilingual learners acquire their languages in both natural and instructed contexts.

Applying Dynamic Systems Theory to Multilingualism

The investigation of the complexity of multilingualism seems to lend itself to being approached from a dynamic systems theory/complexity theory (DST/CT) perspective, a recently much discussed approach in the field of (second) language acquisition research (see, e.g., Larsen-Freeman and Cameron, 2009; De Bot, 2008).

In the Dynamic Model of Multilingualism (DMM) (Herdina and Jessner, 2002) DST/CT is applied to multilingual acquisition and use. Based on DST/CT principles the development of a multilingual system is characterized by its nonlinearity, reversibility, stability, interdependence, complexity, and change of quality. Multilingual systems are adaptive and dynamic, which means that they are able to change depending on the perceived communicative needs of multilingual individuals. This implies that language choices are psychologically and socially determined and are the driving force of language learning and use (see also language mode above) and, furthermore, that the language development of multilingual individuals includes both acquisition and attrition processes.

Systems stability is related to language maintenance, i.e., the stability of a psycholinguistic system is dependent on the requirements of language maintenance, which implies that the system will erode if not enough energy and time is invested into maintaining a system. In DMM language systems are seen as interdependent and not as autonomous systems, as which they are still perceived in mainstream SLA research.

Multilingual proficiency is defined as the dynamic interaction between the various psycholinguistic systems (LS_1, LS_2, LS_3, LS_n) in which the individual languages (L1, L2, L3, L*n*) are embedded, crosslinguistic interaction, and what is called the M(ultilingualism)-factor. The latter refers to all the effects in multilingual systems which distinguish a multilingual from a monolingual system, regarding all those qualities which develop in a multilingual speaker/learner due to the increase in language contact(s). As mentioned above, language contacts depend on the perceived communicative needs of the individual. In other words, the psycholinguistic systems of the multilingual individual, which are in constant change, interact with each other in a nonadditive but cumulative way.

Crosslinguistic interaction in multilingual individuals, which is described as an umbrella term including not only transfer and interference but also codeswitching and borrowing, is also meant to cover another set of phenomena. These are nonpredictable cognitive effects of the development of the multilingual which determine the development of the systems themselves. Such a view is also related, but not identical, with Cummins' Common Underlying Proficiency (e.g., 1991) and Kecskes and Papp's Common Underlying Conceptual Base (2000) (see also Cook above). According to DMM seemingly identical phenomena of transfer can lead to divergent results in different multilingual systems, even if they are transitionally commanded by the same speaker.

One of the key variables of multilingual development and use which was identified as an emergent property of the multilingual system in the DMM is multilingual awareness.

The M-Factor and Multilingual Awareness

The M(ultilingualism)-factor integrates both language-specific and nonlanguage-specific skills used in language learning, language management, and maintenance. Language management skills refer to the integration and separation of language resources and the act of balancing communicative requirements with language resources (see also translanguaging above).

The key factor of the M-effect – as it might also be referred to since it is difficult to decide whether it constitutes a precondition or a result of multilingualism – is metalinguistic awareness or multilingual awareness. It can be defined as the multilingual's ability to focus attention on languages as objects in themselves and consequently to manipulate languages. The domains which can be affected by metalinguistic ability are linguistic development in general, the development of cognitive, metacognitive, and information-processing abilities, and the development of literacy skills.

Prior language knowledge and awareness of this knowledge influence further language learning, in particular learning a second foreign language (Hufeisen and Jessner, 2009). In contrast to monolingual learners, bilingual children show cognitive advantages in further language learning (Cenoz, 2003). Evidence of this was found in investigations into artificial language learning (Kemp, 2007) and a number of studies mostly in the European minority language context such as Spain (Basque Country, Catalonia) and Finland (for an

overview see Jessner, 2008a). In DMM it is argued that in the process of learning an L3 the learner develops a metasystem which is based on a bilingual norm, unlike SLA, where such a metasystem can only be based on the acquisition of the L1 and therefore different in quality. In DST/CT terms this means that the multilingual system is considered sensitive to initial conditions which makes its development difficult to predict (see also Aronin and Jessner, 2015).

Challenges for Future Research

Multilingualism is a challenging field, both because of the complexity stemming from diverse interdisciplinary interests and because of the number of variables involved in multilingualism. But although by now a more realistic view of multilingualism appears to be established as a norm, the monolingual yardstick is still prevalent in most methodologies used in bi- and multilingualism studies.

As suggested by Aronin and Hufeisen (2009), it is absolutely necessary to cross the second threshold, which implies that following the crucial contributions by Grosjean and Cook on the bilingual view of bilingualism as well as Herdina and Jessner (2002), we now have come to see that multilingualism can only be adequately researched by applying a multilingual norm to multilingual research. Linking research on the social level to research on the individual level presents a big challenge for future studies of multilingualism. Also combining the emic, the multilingual's perspective, with the etic, the researcher's perspective, of multilingualism appears to be the most promising step forward in the development of the field (Todeva and Cenoz, 2009).

Aronin and Singleton (2012) put forward a comprehensive view of multilingualism by pointing to the development of (1) a thesaurus of multilingualism, (2) constructs, (3) models specific to multilingualism, (4) working metaphors, and (5) the philosophical level of conceptualization. As depicted in Jessner and Kramsch (2015) it is also necessary to focus more on the so-called dark side of multilingualism and to face the multilingual challenges ranging from individual crises of identity, suspicions of scientific disloyalty to pervasive anxiety that is related to the transition from a monolingual world of identifiable knowledge, predictable monolingual grammars, and clearly recognizable authorities. This new trend in Applied Linguistics, which follows the very positive attitude that has been developed over the years toward multilingualism, also presents a call for a realistic portrait of the phenomenon in question, be it on the familial, the political, the sociocultural, or the scientific level.

Multimodal Therapy in Clinical Psychology

Arnold A Lazarus[†], Rutgers University, New Brunswick, NJ, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Multimodal therapy (MMT) arose out of the realization that there were significant treatment omissions in behavior therapy and in cognitive behavior therapy (CBT). CBT rests on trimodal base – affect, behavior, and cognition. In addition, MMT also thoroughly assesses imagery, sensations, interpersonal relationships, and biological factors resulting in a seven-point diagnostic matrix. This broad-spectrum approach addresses response deficits and excesses, and rests on a social and cognitive learning theory base. While eschewing theoretical integration, multimodal therapists may borrow effective strategies from diverse theories without buying into the theories that spawned them – technical eclecticism. Follow-ups indicate that by working multimodally, clinicians are apt to achieve durable results.

When follow-ups on a variety of clients who had received standard behavior therapy revealed that many were apt to suffer setbacks within 6 months to a year, investigations into the reasons behind this lack of durability revealed that treatment omissions (e.g., leaving several response deficits untreated) lay behind most of the relapses (Kwee and Lazarus, 1986). The behavioral treatment repertoire during the 1950s and 1960s glossed over or completely disregarded many cognitive variables, sensory responses, mental images, and interpersonal factors. Thus, agoraphobic clients received relaxation training, imaginal, and *in vivo* desensitization, and between-session homework assignments to consolidate and augment whatever gains ensued. Virtually no attention was paid to cognitive mediation (e.g., negative automatic thoughts, dichotomous reasoning, unrealistic expectations, and other self-defeating beliefs). Similarly, interpersonal processes (other than unassertive behaviors) were given short shrift (e.g., marital discord, familial tensions, the impact of authority figures, or sibling rivalry). Unaddressed and untreated, these issues, when triggered, retained the power to undermine whatever treatment gains had accrued.

Enter Cognitive Restructuring and More

By the mid-1970s, cognitive-behavior therapy had replaced behavior therapy as the accepted designation, and the field became trimodal – emphasizing affect, behavior, and cognition. This remains true to this day. Nevertheless, Lazarus (1971, 2005, 2006) has contended that equal weight should be given to imagery, sensations, interpersonal relationships, and biological considerations thus operating from a seven-point multimodal perspective (behavior, affect, sensation, imagery, cognition, interpersonal relationships, and drugs/biological factors). Using the easy-to-remember mnemonic acronym BASIC I.D. (taken from the initial letters of the foregoing modalities), the multimodal framework emphasizes the discrete and interactive impact of these seven modalities. The 'D' has contended that equal weight should be given to imagery, sensations, interpersonal relationships, and biological considerations thus operating from a seven-point multimodal perspective (behavior, affect, sensation, imagery, cognition, interpersonal relationships, and drugs/biological factors). Using the easy-to-remember mnemonic acronym BASIC I.D. (taken from the initial letters of the foregoing modalities), the multimodal framework emphasizes the discrete and interactive impact of these seven modalities. The modality underscores that prescription drugs are the most commonly used biological intervention, but nonetheless one must not lose sight of the entire medical panoply. Whenever feasible, multimodal therapists will employ empirically supported techniques, or refer out to an expert, when necessary, to implement a specific procedure. The aim, however, is to think in BASIC I.D. terms to ensure thorough and comprehensive assessment and treatment coverage.

Who Might Benefit from This Approach?

Most clients are likely to show positive gains when receiving a broad-spectrum treatment in which salient issues are addressed (Goldfried and Davison, 1994). Follow-up studies that have been conducted since 1973 have consistently suggested that durable outcomes are in direct proportion to the number of modalities deliberately traversed (see Lazarus, 1997, 2005, 2008). Although there is obviously a point of diminishing returns, it is a multimodal maxim that the more someone learns in therapy, the less likely he or she is to relapse. To reiterate, it appears that lacunae or gaps in people's coping responses were responsible for many relapses (Lazarus, 1981).

Contraindications of the Treatment

People in crisis require the therapist to focus immediately on the precipitating circumstances and events. There is often simply no time to dwell on the vicissitudes and nuances of the BASIC I.D. These cases require and may demand instantaneous relief from their untoward anxiety and depression. Less acute issues and much less dramatic problem areas may call for unimodal or bimodal interventions. For example, clients in a smoking cessation group, in terms of treatment adherence, are likely to respond better to structured methods of habit control than to a broad band of assessments and interventions

[†] Deceased.

(see Rudolph, 1985). And when dealing with frankly psychotic (e.g., schizophrenic) individuals, or with those who are in the manic state of a bipolar disorder, the first inroad should probably consist of supportive treatment and biopsychiatric interventions (Mueser and Gingerich 2006). When appropriate medications have taken effect, a multimodal treatment program may then be instituted to remedy excesses and deficits that may precipitate or aggravate the patient's initial or major complaints.

Theory and Mechanisms

The BASIC I.D. or multimodal framework rests on a broad social and cognitive learning theory (e.g., Bandura, 1977, 1986) because its tenets are open to verification or disproof. Instead of postulating putative unconscious forces, social learning theory rests on testable developmental factors (e.g., modeling, observational learning, the acquisition of expectancies, operant and respondent conditioning, and various self-regulatory mechanisms). It must be emphasized that while drawing on effective methods from any discipline, the multimodal therapist does not embrace divergent theories but remains consistently within social-cognitive learning theory. The virtues of technical eclecticism (Lazarus, 1967, 2005, 2008) over the dangers of theoretical integration have been emphasized in several publications (e.g., Lazarus, 1989, 1995; Lazarus and Beutler, 1993).

The major criticism of theoretical integration is that it inevitably tries to blend incompatible notions and only breeds confusion (see Beutler et al., 1995). The main claim is that by assessing clients across the BASIC I.D., one is less apt to overlook subtle but important problems that call for correction, and the overall problem identification process is significantly expedited.

Afterword

The best controlled study on MMT to date was completed in July 2013 in Iran. Dr Faisal Alzarrad and Houssam Alcharif (of Al-Ahliyya University) were the principal investigators who persisted with the study despite what they referred to as "difficult unstable life conditions." The title of their study is "Effectiveness of a clinical multimodal treatment package on a sample of obsessive-compulsive disorder patients." The purpose of their study was to examine the effectiveness of MMT in reducing symptom severity and improving quality of life in a group of obsessive–compulsive disorder patients. In their study, 20 patients were randomly divided into two equal groups wherein 10 patients were treated with a medication regimen, and the experimental group received MMT as well as medication. Results on pre- and posttests indicated significant effects in the group receiving MMT. The data indicated a 60% reduction in symptom severity and a 74.4% increase in quality of life relative to the medication only group. A 1-month follow-up showed stable outcomes. The study was accepted for publication by the Association of Arab Universities in their *Journal for Education and Psychology*.

Multinational Corporations

Abstract

A multinational corporation (MNC) is an organizational vehicle to transfer knowledge from one country to another while preserving cash flow and control rights. The MNC has its origins in the uncertainty of international trade and investment, and its modern form coevolved with the emergence of institutional and political structures that permitted owners to realize and retain profits from the utilization of its organizational knowledge in foreign countries and territories. Since operating overseas incurs costs, the MNC is only viable if its transfer of organizational capabilities permits it to compete effectively against domestic and other foreign competition. With the diffusion of knowledge, local competitors often compete with the MNC in the long run. However, an MNC has the advantage of profiting from arbitraging across markets and leveraging its scale and scope globally. The impact of the revolution in information technologies has consequently an ambiguous effect, both enabling the MNC to operate globally more effectively and enabling markets to contract to more efficiently compete against organizational solutions.

A multinational corporation (MNC) is the organizational form by which the knowledge of *how to coordinate and organize work* is transferred from one national institutional setting to another (Kogut, 1992). It represents, on the one hand, the evolution of organizational mechanisms by which to resolve the historical hazards of long-distance trade and investment. On the other, it is the vehicle for the transfer of organizational knowledge and practices. This transfer initially is from the home country to foreign sites, but eventually can consist of the diffusion of organizational and technological knowledge within a transnational network. In this dual role of providing a private ordering of exchange and as a vehicle for the diffusion of organizational practices, it challenges the power of the state and the resident national institutions and frequently is the intended or unwitting agent of social, economic, and political change in the world economy.

Contrary to the emphasis on the transfer of organizing knowledge, the conventional and complementary economic definition stresses the ability of owners and their managerial agents in one country to *control* the operations in foreign countries. There is a frequent confusion that equates the ability to control with the flow of capital across national borders. Since Hymer's thesis (1976), it is recognized widely that capital flow is not the distinguishing characteristic of a MNC (*see* International Business). Capital can flow from one country to another in expectation of higher rates of return. However, this flow may be invested in the form of bonds, or in equity amounts too insignificant to grant control to foreign owners. In this case, this type of investment is treated as a 'portfolio' investment. The central aspect of 'direct investment' is the ownership claim by a party located in one country on the operations of a foreign firm or subsidiary in another. The MNC is, thus, the product of foreign direct investment (FDI), which is defined as the effective control of operations in a country by foreign owners.

The economic definition, however, does not capture the importance of the MNC as the organizational mechanism by which different social and economic systems confront each other. The MNC, because it usually develops in the cultural and social context of one nation, exports its organizational baggage from one institutional setting to another. In this regard, it plays a powerful role as a mechanism by which to transfer organizational knowledge across borders. However, while being foreign implies that it might serve the valuable role of importing new practices, its foreign status also implies that its practices are likely to conflict with existing institutions and cultural norms. Moreover, since MNCs are often large, they pose unusual challenges to national and regional governments who seek to maintain political autonomy and yet are often anxious to seek the investment, technology, and managerial skills of foreign firms.

There are, thus, economic and sociological definitions of the MNC that differ, and yet complement, each other. In the economic definition, the MNC is the control of foreign activities through the auspices of the firm. In the sociological definition, the MNC is the mechanism by which organizational practices are transferred and replicated from one country to another.

Early History

The MNC is defined in some sense arbitrarily by where frontiers are drawn. In ancient Greece, these frontiers were the borders among city-states. In imperial Rome, the new administrative units of an expanding empire and its external boundaries defined the borders. Political borders correspond only approximately to the distribution of cultural and ethnic dispositions. The history of the MNC is tied closely to the origins of trade in and between cultural communities, and these communities remain important in many sectors in the modern economy.

Early trade was often characterized by the difficulty of transacting across borders. Trading has always instigated from the unequal and varied distribution of resources across geographies. The trading of salt was an important factor in most continents and still can be found in rather ancient forms in east

 http://dx.doi.org/10.1016/B978-0-08-097086-8.73004-2

Africa. Towns, such as Salzburg, owed their origins to their fortuitous access to salt mines.

This unequal distribution incited traders to travel long distances and undergo unusual risks for the hope of gain. The dilemma is quite apparent. How can markets for trade develop between distant cultures? Indeed, there is good evidence that early trading was quite precarious. Brown (1969) notes that Hermes was not only the God of messengers but also the God of theft and trade. He was often worshiped at borders, marking the place of trade. Herodotus describes the practice of 'silent trade' of goods at boundary markings in which one party would deposit its goods at the border and the second party would later deposit a corresponding offer. The original party might accept this bid, take the goods, and leave its initial offer. Clearly, only a strong demand for unusual foreign goods could sustain such a treacherous institution of transaction.

Not surprisingly, Curtin (1984) doubts the accuracy of this account. Instead, he stresses the importance of ethnic groups, such as the Gujarati or overseas Chinese, or the force of imperialism and military power as ways in which 'cross-cultural trading' was permitted to develop. But such solutions remained fragile, with foreign enclaves and ethnic groups subject to local hatred and military rule often confronting competition from other powers.

Yet, trade persisted through the centuries. Indeed, the demand for foreign goods was so strong that incredible profits could be realized by international trade. Since transportation was poor, and technology to hold inventories rudimentary, an agent in the right spot at the right time could earn fortunes. And in this laid the great problem. For in times of great demand, prices could rise astronomically, as Braudel (1973) documents in his history of material life. With such distances between the agent and the principal in the exporting country, an agent could easily, and often did, disappear with the profits.

The early solutions were many and provide insight into one of the great properties of the MNC: its ability to organize transactions within its own organizational boundaries. Great fairs were one solution, where principals met their customers in one place. But fairs were intermittent and often distant from final markets. The further development of Roman commercial law during the medieval and Renaissance periods strengthened the liability of the principal and also the legal recourse in principal–agent conflict. However, the application of law between two parties in different legal jurisdictions has always been a difficult form of dispute resolution. In his study of the Jewish Maghrebi traders of the twelfth century, Greif (1989) emphasizes membership in ethnic 'trading communities.' Since ethnic enclaves in foreign sites could monitor the activities of agents, principals could be informed of malfeasance. Agents could then be excluded from future contracts within the community, thus deterring dishonest behavior. Partnerships were also another way in which agents were also bonded to the firm.

Birth of the MNC

However, another solution was the company, where the archetypical cases were the Dutch West Indies and the British East India Company dating from the 1600s and the 1700s. The stock company form permitted the investing of capital in its ownership by outsiders in promise of future dividends. The capital might be raised for a single voyage or, eventually, could be maintained in the company in the form of stock ownership. These companies were primarily engaged in trading, although increasingly they became involved, economically and politically, in foreign countries.

With the evolution of the limited liability law in the nineteenth century, and the diminished role of the state in restricting the growth of the joint stock company, this organizational form expanded rapidly in many European countries as well as in the United States. Along with the growth of equity markets, the financial resources to invest overseas became more available due to advances in the banking system and also in bond markets. Indeed, the great capital needs of the railway industry created an international market for the sale and purchase of railroad bonds. However, international loans and bonds were risky and it was not uncommon for sovereign governments to default, including state governments within the United States.

The increasing wealth of Western countries, along with constraints on the speed by which national industries could absorb new loans, encouraged massive foreign investments by the end of the nineteenth century and the early twentieth century. This was a period of globalization in terms of the percentages of capital outflows to total capital accumulation. Great Britain is estimated to have exported some 25% of its capital prior to World War I and French capital exports were often greater. This capital went to countries hungry to finance their industrial expansion, including the newly industrializing countries of Russia and especially America.

The British were unusual in directing a considerable amount of their outward capital flows in the form of direct investments. A great deal of this investment went into their colonies. Prior to the mid-1800s, companies operating overseas engaged largely in wholesale operations; they did not run factories, operate mines, or own agriculture. The British direct investments were, thus, different than before, as British came to own and run local operations. Moreover, the British invested in South and North America.

The 'freestanding' company, as labeled by Wilkins (1988), was a peculiar form of investment that was quite prominent in many British colonies but hardly unique; thus the French stock market records indicate that many floated companies had no domestic but only foreign activities (Kogut, 1998). The free-standing firm raised capital in the domestic financial market where its administrative office was located, but it operated no domestic activities. All operations were overseas. These companies were multinational in ownership, but uniquely foreign in operations.

The United States offers an unusual case. A rapidly growing country, it imported more capital than it exported up to World War I. However, whereas it imported largely portfolio investments, its outward flows were dominated by FDIs. In other words, American companies showed an early penchant for expanding overseas (Wilkins, 1970), often competing on their organizing advantages. The Singer Company built within two decades of its founding a large factory employing thousands of workers in Scotland. Oil companies, Kodak, Westinghouse, Ford, and mining and agricultural companies all invested overseas. Companies in oil, mining, and agriculture often invested in poorer markets where there were resources to be

found. These early investors were often involved inextricably in the politics of the foreign governments, and the American military itself intervened aggressively numerous times in the Caribbean, Mexico and Central America, and South America. As in the British case, the history of American direct investment occurred in the context of an expanding military presence of the home government. Moreover, since many of these countries were poor, the MNCs responded to the demands of the host nation, especially in the form of concessionary contracts, to provide public services, for example, hospitals, roads, and power (Robinson, 1964). This complicated legacy of the early history of the MNC in Latin America created hostility on the part of the local population that persisted throughout most of the twentieth century.

National Origins and Institutions

It is important to underscore that the MNC usually evolved in the context of specific national institutions, which left an 'imprint' on its organization and capabilities (Westney, 1993). The MNC is a growing firm whose organizational borders have spilled across borders, but whose national imprint still persists. Moreover, since this large firm is usually tied to a larger domestic network of suppliers and customers, its expansion overseas is accompanied by the coinvestments of these other members. This is a pattern seen in American investments in the United Kingdom in the 1950s and repeated by Japanese MNCs investing in the United Kingdom in the 1980s and the 1990s (Dunning, 1993).

Chandler (1990) noted as well that these MNCs reflected the national characteristics of management. In comparing the cases of the largest firms in the United Kingdom, Germany, and the United States, Chandler found that differences in managerial capabilities, reflecting national institutions, explain their success and failure patterns. He particularly criticized the managerial capabilities of British firms, a point not shared by some British historians (Hannah, 1999). But more importantly, Chandler's thesis assumed that size itself constituted the realization of scale and scope of economies instead of the outcome of success and growth. This observation is especially important for understanding the lack of large MNCs in Italy or in Taiwan, both of which have very successful small firm economies but do not have MNCs comparable to other countries of similar levels of economic wealth. Yet, both countries are relatively wealthy and successful, and their many small companies have achieved high rates of exporting. Even in the case of the United States, the evidence implies that American firms, large and small, came to Europe, riding on the back of the national organizing principles of standardization in work methods (Kogut, 1992). Chandler's larger point of the effect of national systems on firm capabilities is largely accepted; his belief that large firms reflect better management because they achieve scale is disputed far more.

Organization of MNCs

The national origins of the MNC influence their subsequent organizational evolution. In the United States, the great post–World War II expansion of MNCs coincided with the diffusion of their adoption of the multidivisional structure. Indeed, the refinement of 'organizational technologies' permitted American firms to manage their rapidly growing operations on a worldwide basis.

The young American MNC began with little knowledge and experience of the foreign market. Initial foreign sales are exports executed within the existing organizational structure. These structures could be functional (e.g., organized by production and sales) or divisional (e.g., organized by geographic area or product division). As foreign sales increased, an international division was created to make the sale and to provide customer support. In consequence, the domestic organizational unit would sell to the international division its products at an internal 'transfer price.' As this price was set by the domestic market, it was unlikely to reflect the competitive conditions in the foreign country. Moreover, the products were often not designed to the tastes of foreign demand. Because of this internal conflict, the American MNC would replace the international division by transferring responsibilities to area divisions (e.g., Europe, Asia, South America) or to product divisions (Stopford and Wells, 1972). While these structures diminished the internal conflict, they ran the hazard that the divisional managers across areas did not cooperate or that managers across product divisions tended to fall back upon focusing on the home market.

European firms grew up in a different environment. Europe was a highly unstable continent during the twentieth century, with significant political and economic conflicts. Borders sometimes changed, and they also marked the necessity to pay commercial duties. The gradual creation of the European Union in the last third of the twentieth century eliminated tariffs and lessened national differences. This history marked their firms. The organizational technologies in most of these countries were quite different from those found in the United States. Holding company structures were common, banks or other financial institutions played powerful roles in ownership and cross-holdings, and firms were tied together in complex financial webs. These structures, often called 'mother–daughter' organizations, reflect the linguistic terms used in northern Europe to describe headquarters and subsidiary. These mother–daughter structures consisted often of a headquarters that held a portfolio consisting of ownership control over dozens of companies, many of them in the same sector but located in different countries. Reporting relationships among these companies and headquarters was less formal than found in American companies, and control was often exercised through the movement of managers who were lifetime employees. These structures were often seen as inefficient, especially compared to the size and organization of American multinationals that were investing rapidly in Europe at this time. European critics called for the restructuring of the European firms and industry along American lines.

The structure of Japanese companies also reflected their historical origins. In Japan, the trading company performed an extraordinary role in the exports during the first two-thirds of the twentieth century. These companies started primarily as wholesalers, but over time developed their own industrial companies located in Japan and eventually overseas. Though the forced imposition of American antitrust law after World

War II disrupted these patterns, trading companies and other affiliated company networks, called *keiretsu*, reconstituted the earlier pattern of constellations of domestic companies competing in home and, through their trading companies, in foreign markets. As in the American and European cases, Japanese firms varied in their internal structures, with functional and even factory-based organization being the predominant structures. Still, a dominant trend emerged over time as the role of trading companies declined, especially for the exportation of industrial and high-technology goods. This trend consisted of the appendage of an international division to the existing structure (Suzuki, 1991).

These different national structures confronted an increasingly more globally integrated environment in the course of the twentieth century. This environment posed the classic organizational problem of balancing integration and differentiation. For the MNC, this problem posed itself as meeting the demands to achieve global scale against the needs of national markets and governments. Given different national principles of organizing the activities of MNCs, there was not a rapid convergence to a global structure. The growth of MNCs, especially in Europe, was stymied by these traditions. Continuing national differences and the failure to develop harmonized European corporate law deterred the emergence of pan-European MNCs. Many of the most important cross-European mergers in the 1970s failed within a decade. Instead, American MNCs, less bound by these separate national traditions, were able to create integrated European strategies.

Nevertheless, it was in Europe where new organizational structures developed to resolve the conflict between integration and differentiation. MNCs from smaller countries offered the laboratory experiments that influenced the evolution of MNCs from larger nations. Because of the small size of many European countries, large firms in Sweden, Switzerland, and the Netherlands quickly became MNCs, and these corporations had far more assets and employees outside their home countries than within. Over the course of the last two decades of the twentieth century, organizational structures developed, labeled as transnational corporations, that distributed global responsibilities to national subsidiaries, created global teams and projects, and encouraged the transfer of 'best practices' across borders.

Diffusion of Organizational Knowledge

In its evolution the MNC is not without serious contradictions. Evolving from its national context, the MNC employs large numbers of employees of diverse nationalities and ethnicities. Westney (1993) notes that a subsidiary is, thus, caught between the institutional pressures to conform to the company norms and values and to the cultural and social influences of its local national environment. At the heart of the evolution of the multination corporation, thus, lies the tension between national institutions and the fragile emergence of a global culture.

The international evolution of the organizational structures of American multinationals mirrored, as is noted above, the broader diffusion of organizational technologies in the home market. The initial investments by a firm took place, often, on the basis of opportunity and the extension to familiar countries. Much like the ethnic trading communities dating back to the earliest times, the inexperienced MNC preferred countries that are culturally similar to what their managers know at home (Johanson and Vahlne, 1978). In these countries, they often established foreign enclaves where their expatriate managers could live in the simulated familiarity of their home environments.

The relevance of the second definition of FDI as the transfer of organizational knowledge is critical to understanding the powerful conflicts posed by the MNC. The MNC, competing often on superior technologies and managerial capabilities, serves as a conduit of knowledge across borders. Some kinds of technologies can be purchased on markets and the flow of licensing payments attached to the sale of the right to use a technology constitutes a nontrivial flow in international balance of payments. Technology can also flow by the movement of people. Just as English craftsmen were imported by continental Europe in the early industrial period, there exists an international market for managers and skilled workers.

However, some knowledge is embedded in organizations and can only be transferred as an organization across borders. The issue is more than whether knowledge is tacit or explicit, for this pertains to the knowledge held by individuals too. The central feature of the diffusion of knowledge by the multinational is that it transfers the knowledge of how to organize and how to coordinate people and across divisions. These organizing principles then provide the capabilities for the firm to achieve quality, speed products to the market, or lower costs (Kogut, 1992). For this the MNC is required, which through its own activities or in joint ventures with host companies, transfers the organizational knowledge.

The global market for knowledge also extends to consultants. The large American consulting practices often have their origins in their acquisition of American organizing principles that they then transferred around the world. The international diffusion of the divisional structure, for example, reflects the knowledge acquired in American consulting practices that was then sold abroad. Channon (1973), for example, observes that half of the firms he observed as adopting the divisional structure relied upon the consulting services of the same American firm. Similarly, British and then American banks spread throughout the world on servicing the needs of their expanding home clients, and then on transferring their practices into these countries (Jones, 1993).

It is important to realize that once this transition period passed, the MNC and multinational service firms, such as those engaged in consulting, banking, and advertising, had permanently and historically changed the global economy. No longer was the flow from the United States to Europe or from one ethnic community to another. The network of connections developed by the MNC permitted the flow of ideas and practices among and between countries. Thus, whereas it took half a century for American practices to diffuse to Europe, the introduction of quality circles from Japan happened within a decade or two of their original innovation. In Europe, Japanese innovations were often diffused by American firms, including consulting companies.

However, this image of the free flow of knowledge needs to be strongly conditioned on the continuing importance of

national institutions. Nations consist of defined cultures and economic and social institutions, such as unions, financial systems, and religious values. These institutions interact and their complex interactions causally influence behaviors. For example, the German system of centralized bargaining, enterprise clubs, strong banks, and social welfare has, until recent times, composed a national configuration of institutions that influences the capabilities of resident firms to be able to manufacture high-quality goods for export markets (Streeck, 1995; Soskice, 1990). The introduction of Japanese and American teams confronts in Germany the presence of existing work councils. These councils are fairly rigid features of the German environment. Since Japanese methods may not be effective without teams as complementary factors in organization, this institutional refusal can effectively deter the diffusion of these methods. In short, national organizing principles are embedded in the wider social institutions. Inconsistency between these institutions and principles, then, is an empirical question of the bargaining strength of vested powers.

Economics and Politics of MNCs: the Role of CSR

Since the MNC is intrinsic to FDI, theories of FDI must account for why one country invests in another and why this investment is carried out within organizational boundaries of a firm (see Buckley and Casson, 1976; *see* Foreign Investment: Direct). In distinguishing between portfolio and direct investment, Hymer noted that firms operate at a disadvantage in foreign markets and hence they must have an offsetting competitive advantage to compete overseas. These advantages for overseas investments are the same ones that allow a firm to compete and grow in the home market. These observations have important implications. The first is that direct investment is the growth of the firm across borders and hence the firm expands internationally on what it has learned at home. This observation is the basis for the evolutionary theory of the firm. The second observation that Hymer made is that firms that expand overseas, because they have competitive resources, are also likely to be large and to belong to oligopolistic industries.

In these observations, we can understand the ambivalence expressed in popular and policy debates regarding the MNC. Competition among MNCs often is the extension of their home domestic and oligopolistic rivalry that spills across national borders. In many global industries, the same company names dominate each country's list of the largest firms inside their national frontiers. No matter if it is Poland or France, Singapore or Mexico, the same MNCs will be found in the local oligopolistic industries (e.g., consumer goods or automobiles). Because they are large even in their home markets, investments by MNCs can have a large impact on a host country (Caves, 1974).

As a consequence, the MNC has often been the subject of debates concerning national sovereignty and welfare. In recent decades, acquisitions have generally been the primary way by which multinationals invest in wealthy foreign countries, where the vast proportion of direct investment is concentrated. Given the size of a MNC and occasional national importance of the targeted acquisition, even wealthy countries frequently evidence discomfort, if not outright public hostility, to multinational investments. Moreover, MNCs are sometimes the vehicles for foreign policies of their home or host country. The decision, for example, of the United States to embargo technology and investment flows to Cuba, the former Soviet Union, Iran, and other countries periodically has caused conflict with other countries.

MNCs are especially problematic in developing countries. By definition, developing countries are relatively poor, thus both in need of capital and concerned over their loss of independence. As discussed above, the history of MNCs in developing countries is marked by its origins in policies of imperialism and colonialism. Especially in Latin America, where a school of thought labeled *Dependencia* has been influential, the concern over dependence on the United States resulted in efforts to curb the power of the MNCs by restricting the amount of equity ownership a foreign firm could hold in a domestic company or by prohibiting investment in certain sectors. Mexico's constitution forbids foreign investment in the oil industry; Brazil pursued for a long time a policy to restrict foreign participation in the electronics industry.

The other side of the coin is that MNCs bring investment and technology to the foreign country. Vernon (1966) hypothesized that innovations start in wealthy countries. As the market is saturated and as oligopolistic rivalry increases, MNCs are pushed out from their home markets to expand abroad in new markets and to locate less expensive places. Thus, Vernon seized both sides of the debate, not only recognizing the value of the transfer of technology but also emphasizing the oligopolistic nature of multinational investment.

It is, in fact, difficult to draw simple conclusions regarding the relationship of foreign investment and national growth. Countries such as Singapore, Malaysia, and Thailand have encouraged FDI actively. The growth in China's coastal sector is indisputably linked to the massive investments by MNCs. However, historically, Japan and Korea have pursued more cautious policies regarding investments by MNCs. In these countries, the state has often negotiated the terms for entry by MNCs, sometimes requiring licensing to domestic competitors as a price. The efficacy of such policies for these countries is much disputed. However, for many other countries, the intervention of the government in demanding licenses unquestionably leads to internal corruption and to insufficient domestic competition.

MNCs have a natural incentive to collude with corrupt or failed governments or to pursue 'regulatory arbitration' that leads to locating in countries with poor labor and environmental standards. Consequently, the past decades have seen the rise of nongovernmental organizations (NGOs) that seek to pressure MNCs into improving ethical practices into their operations. Pressure tactics consist of publicizing bad practices and thereby damaging the value of brand labels, or lobbying national and international regulatory agencies. Many companies, such as Walmart and Nike in the United States, have claimed to have dramatically improved labor and ethical standards in their own operations and also those in their supply chains. In many cases, NGOs act as partners to MNCs to help them monitor the standards of suppliers or to help them deliver drugs to remote areas in developing country. A particularly interesting partnership is the cooperation between

international agencies, such as the World Health Organization, and private companies for the provision of aid through humanitarian supply chains (Van Wassenhove, 2005).

Institutions and MNCs

There are many channels by which a country can absorb foreign technology and managerial techniques. Most of the evidence shows, however, that prohibitions on the inflows of direct investment can be very costly for many countries. With their domestic industries still to be developed, a developing country requires substantial investment. Some countries, primarily in Asia, have been able to achieve very high savings rates to finance their industries without direct investment. Moreover, high savings rates, plus political stability, create growth, and growth attracts foreign portfolio capital. A poor country that prohibits FDI but does not have high rates of saving entirely depends on portfolio capital. The history of debt and currency crises in the 1990s convinced many poor countries that FDI was a preferable means of attracting capital, because it could not be easily pulled out of a country on short notice in response to a financial crisis.

However, MNCs also respond to the volatility in the global market. This volatility derives from changes in exchange rates, politics, and productivity. Having achieved sufficient experience and having established subsidiaries around the world, the MNC might choose to close a plant in one location and open plants in new locations (Kogut and Kulatilaka, 1994). Of course, such actions might provoke a response by labor, but historically, labor has been organized by national, not by international, organizations (Martinelli, 1975). Yet, there is also the possibility that locations lose some kinds of plants but gain more sophisticated investments. Cantwell (1989) proposed that some regions and countries pull multinational investments. Yet, it has long been noticed that FDI among developed countries flows to high-cost locations. Regions such as Silicon Valley, Baden-Wuertemberg, and Singapore attract multinational investments not because wages are low, but because productivity levels are high and workers are well trained.

MNCs are not only drawn to regions with high agglomeration but also contribute to these clusters through technology transfer and diffusion. For example, Blalock and Gertler (2008) estimate that about a third of output growth in a sample of Indonesian firms is due to gains in technology diffusion to local firms. It is an interesting question though whether MNCs agglomerate in traditional domestic firm clusters or in clusters dominated by MNCs. Alfaro and Chen (2009) analyze this question, finding that MNCs are more strongly attracted to MNC clusters in which technology diffusion plays an important role. This is an intriguing result that suggests that MNCs shape the global economic landscape.

A related and persisting literature concerns the competing effects of multinationals on crowding out domestic firms and technology spillovers. Kosova (2010) found that in the short run, foreign entry does crowd out domestic firms, but that after entry, multinational investment increases demand and the survival of domestic competitors; this work thus also confirms, as discussed above, that FDI is a mode of technology and knowledge transfer. Chang and Xu (2008) analyzed a similar question for China, finding that foreign entry crowds out regional but not national domestic firms. On the contrary, foreign entrants face enhanced competition from 'reformed' Chinese firms, which moved from state ownership to greater private control.

This last observation of the enhanced capabilities of domestic firms in China points of course to one of the most important changes in the composition of FDI. Increasingly, developing countries have given rise to their own MNCs acting in the region and sometimes globally, a trend that has boomed since analyzed by Lall (1983). Often, the MNC acts as a training center in the developmental strategies of emerging economies. Similar to the history of firms from early developed countries, the MNCs from emerging markets grow often aggressively through mergers and acquisitions, such as the acquisition of Jaguar and Rover operations in the United Kingdom by Tata, of Volvo by the Chinese firm Greely, or of IBM laptop computer operations by Lenovo also from China. Firms such as the Brazilian Embraer in aircraft, the Korean electronics firm Samsung, and the Chinese white good manufacturer Haier are major competitors in their respective markets, as are some firms from the so-called 'transition economies,' such as the Russian energy company Gazprom. The analysis of the imprinting of the national origins and their competitive advantage of these firms is a major current research area.

Globalization and the Digital Information Economy

The peculiar conflict in the world economy is the growing trend toward economic integration without a concomitant growth in global political and social institutions to regulate and arbitrate this trend. MNCs are rapidly adopting advanced information technologies to increase the efficiency and capabilities of their operations. Valuable information, such as software or financial services, is transmitted digitally. Governments are often unable to tax the value of these services or control their content. Moreover, information technologies, often supported by private telecommunication networks, permit, for example, a unit in Germany to control the manufacturing operations located in Brazil.

Digital technologies permit a high degree of integration and, in the short run, aggravate the gap between countries that are rich and those that are poor and do not have the infrastructural capabilities. However, these technologies are beginning to have profound effects on some regional economies. In parts of China, India, Israel, and elsewhere, advanced satellite transmission transmits digitally encoded work between their sites and other organizational units of MNCs located elsewhere. Earlier the Indian engineer from Bangalore might have tried to migrate to the United States to bring his human capital to a more attractive labor market, whereas the increasing wages and job prospects in India are encouraging many to stay at home and participate digitally in the world economy.

These trends have unclear effects on MNCs. They permit more easily the development of projects that are in continual development, as work passes from one unit to the next as the day advances. They also allow more easily the coupling of less

expensive labor in one country with more expensive skilled labor in another.

At the same time, the origins of the MNC laid in its ability to organize labor on a worldwide basis on principles other than ethnic and cultural identities. This organization has never been without cost and risk. The growth of a world digital economy permits alternative ways by which labor can cooperate and be coordinated on a world basis. The intriguing question at this point in history is whether the MNC, though still a vital presence in the world economy, nevertheless, will recede relatively in importance as information technologies reduce the meaning of geographic distance.

Abstract

An overview of the current state of multiple comparisons is given, with special application to the social sciences. The problems caused by multiple comparisons are detailed, and Bayesian and frequentist solutions are discussed. Special emphasis is given on definition of the 'family' of statistical inferences, as well as on pre-registration of studies.

Introduction

'Multiple comparisons' (hereafter abbreviated MC) refer to making multiple inferences, and the 'MC problem' refers to errors that can arise in that case. MC arise in virtually all statistical studies, because it is extremely rare that a researcher will make only one claim from their data. For example, in multiple regression analysis one considers multiple inferences for the regressor variables X_j on a response Y; in meta-analysis, one considers multiple inferences concerning effects of a single X on a response Y in different settings; in a subgroup analysis, one considers multiple inferences about one or more X variables in data subgroups (male, female, young, old, etc.); and in an experiment, one considers multiple inferences about differences between the means of various treatment groups (A versus B, A versus C, B versus C, etc.). The MC problem arises in variable and model selection as well where there are inferences about literally millions of different models, often performed automatically. MC problems also arise when a researcher performs multiple tests of the same hypothesis – parametric, nonparametric, or covariate-adjusted using different covariates, for example.

MC are not restricted to a single study of data in a researcher's hands: The 'file drawer' effect (Sterling et al., 1995), where the occasional 1 out of 20 erroneously significant studies are published, and the remaining 19 out of 20 correctly insignificant results remain in 'file drawers' of researchers at various universities, is also a manifestation of the MC problem. Neither are MC restricted to concerns over erroneous $p < 0.05$ significances: It is common (but extremely misguided) practice in the social and behavioral sciences to declare regressor effects as 'different' if one is significant ($p < 0.05$) and the other is not ($p > 0.05$), and this is another error that occurs with multiple inferences (Gelman and Stern, 2006; Freedman, 2005).

While the consequences of MC are more broad as suggested above, one of the problems resulting from MC can be illustrated with a simple probability calculation: If k null hypotheses are tested, each at the $\alpha = 0.05$ significance level, then the probability of erroneously rejecting one or more hypotheses is $1 - (1 - 0.05)^k$ under independence. With $k = 14$ hypotheses, the false positive probability is 51%, and with $k = 45$ the probability jumps to 90%. This probability calculation shows how easy it can be to 'rescue' a study where there are truly no effects: By looking at the data from numerous angles, performing multiple tests, erroneous statistical significance is virtually assured.

Another way to view the MC problem, one that does not require an assumption of independence, is to recognize that p-values are uniformly distributed between 0.0 and 1.0 under their respective null hypotheses (e.g., Westfall et al., 2011, p. 4). Thus, one may expect that 5% of them will be less than 0.05 when there is no true effect, no matter what is the dependence structure.

Recently, MC have received much attention in the biological sciences, spurred by problems of multiple inferences with genetic data, where the number of genes evaluated in a study can be easily in the thousands. In this case, even if the genes tested are unrelated to the biological phenomenon, hundreds of p-values will erroneously indicate significance at the 5% level. It is now standard in such analyses to adjust for the MC problem (Efron, 2010). Similarly, with neuroimaging studies where multiple tests are performed at thousands of brain locations, adjustment for MC is considered mandatory (Bennett et al., 2009).

MC have received less attention in the social sciences. Null hypothesis significance testing in general has been disparaged in this literature (Nickerson, 2000), leading many social science researchers to think that multiplicity adjustment is not needed, simply because testing itself is not needed. Indeed, there are several valid reasons for avoiding statistical tests, including concerns about practical versus statistical significance, the implausibility of the precise null hypothesis, and general confusion over the meaning and interpretation of p-values.

But on the other hand, concerns over replicability have recently surfaced in the social and behavioral sciences (Bohannnon, 2014). Multiplicity and replicability are intimately related: If a test erroneously indicates significance, as is likely to occur with MC, then that test result will not replicate in 95% of future studies. But the multiplicity/replicability problem is not restricted to tests. Any evaluation of statistical data from multiple angles, and selection of the 'best' angle for presentation, however 'best' is defined, will necessarily present a biased view, one that will tend not to replicate. This phenomenon is also known as 'regression to the mean.' In the medical literature, Ioannadis (2005) found that even in a selection of randomized comparative trials, the gold standard for biomedical research, results replicated in only 19 of 28 (67.9%) follow-up studies. For observational studies, which are more commonplace in social and behavioral sciences, Ioannadis noted a paltry 1 in 6 (16.6%) replication rate. Bohannon (2014) reports a similarly alarming replication failure rate of

more than 33% in a selected group of popular social psychology studies.

The most important take-home message for researchers in the social sciences about MC is simply this: The MC problem makes it easy to do sloppy, nonreplicable science. It is very easy to get nice-looking results, whether in terms of small p-values (or large p-values, if model confirmation is needed), or large effect sizes, with multiple looks at the data, followed by judicious selection of the results that the researcher wants. The incentives to do so are great (grants, tenure, promotion), while the penalties for not doing so are unfortunately scant, particularly in the social sciences where replication of studies is not practiced as much as it is in the medical literature. Glaeser (2006) and Simmons et al. (2011) note that such researcher incentives are likely to blame for much bad science. Taken to its extreme, the culture of multiple selective inferences includes selective exclusion of data to make results look better; an example was recently reported in which a researcher claimed that "in the area of marketing and (to a lesser extent) social psychology, many consciously leave out data to reach significance without saying so" (Enserink, 2012).

Prespecification of a Family of Inferences

Multiple comparisons procedures (MCPs) are methods to correct for problems that arise when there are multiple inferences. As with all inferential methods in statistics, there are frequentist and Bayesian methods to correct for MC. Methods that control the familywise error rate and false discovery rate (FWER and FDR respectively, defined below) are primarily frequentist. There are many Bayesian methods for dealing with multiplicity, a primary one being hierarchical modeling (Gelman et al., 2012), which attempts to solve the multiplicity problem through shrinkage estimation, discussed further below.

To use any of these methods for MC, the researcher must prespecify a *family* of inferences to be considered in the study. With frequentist methods, one must determine k, the number of inferences in the family, and the adjustments for MC typically involve dividing the error rate α by functions of k. With Bayesian methods, one must specify the joint likelihood and multivariate prior for the k parameters of interest, and then allow the multiplicity adjustment to take place automatically through Bayesian posterior inference.

Prespecification of the family is the most difficult and controversial aspect of MCPs. It is rare in the social sciences to prespecify data analysis plans (DAPs), but there are growing efforts to make pre-registration a prerequisite for publication (Bohannon, 2014). But even with pre-registration, it is difficult to decide exactly which inferences should be included in the MC family. For example, an experiment might consider the effects of three treatment variables on a sample of men and on a sample of women. There are three treatment comparisons within each sex, AB, AC, and BC. Should the family include $k = 6$ comparisons? Or should there be two families of $k = 3$ each, one for men and one for women? Unfortunately, there is no obviously right answer to the question in general, and the consequences of one choice over the other may be great: It can happen that there are no statistical significances when adjusting for MC using a family of $k = 6$, while everything is significant when adjusting for MC using two families of $k = 3$.

The pharmaceutical literature provides some guidance for choice of a family. In clinical trials, it is often required to pre-register a study with the regulatory agency. Such pre-registration includes medical details and statistical details, including sample size determination, statistical models to be used, and even a statement concerning whether and how MCPs are to be performed (ICH, 1998). Westfall and Bretz (2010) provide guidelines as to which medical endpoints should be considered a family, for the purposes of drawing multiple inferences. They state that this family must include all efficacy endpoints (primary and secondary) for which medical or marketing claims will be made, following conclusion of the study.

Applying the lessons from the pharmaceutical industry to research in the social sciences, one might suggest that journals require prespecifications of DAPs as a prerequisite to publication. These DAPs should include similar information as in pharmaceutical DAPs, including a statement as to which tests are considered a 'family,' and how multiplicity adjustment is to be performed. Taking the analogy from the pharmaceutical industry, one might suggest that a research claim of a social science study can be made only if the inference was included in the family, as defined in the pre-registration. Any other claims are disallowed.

Further guidance on choice of a family is given by Westfall et al. (2011, p. 33). There, the authors substitute the word 'question' for 'inference':

- The questions form a natural and coherent unit.
- The questions are considered simultaneously in the decision-making process.
- The questions form a set over which you play 'pick the winner.'

Of the three above, the third provides the clearest guidance. For example, in the description of the experiment above, if the researcher was willing to make (and publish) any claim of a difference between any two treatments, for either sex (even if there was just one such significance), then the family clearly must contain all $k = 6$ inferences across both sexes, even though classical methods such as Tukey's method for MC do not cover this case. Alternative methods are needed in this case, and fortunately they are readily available (Westfall et al., 2011).

FWER and FDR

In statistical hypothesis testing, a Type I error is the outcome of erroneously rejecting a true null hypothesis. The FWER and FDR provide different characterizations of Type I error rates when there are multiple inferences.

Once the family is prespecified, the future outcomes of the inferences appear as shown in **Table 1**. There are k total hypotheses, of which (unbeknownst to the researcher) k_0 are true nulls and k_1 are true alternatives. Suppose the hypotheses are tested by whatever method, multiplicity adjusted or not. Then after the study, the researcher will reject a random number R of hypotheses, and make claims concerning them. Of these R

Table 1 Outcomes of inferences from a prespecified family

		Action		
		'Accept' H_0	*Reject H_0*	*Total*
State of nature	H_0 true		V	k_0
	H_0 false			k_1
	Total	$k-R$	R	k

rejections, a random number V of them will be erroneously rejected. The remaining entries inside the table are deliberately left blank to avoid unnecessary symbolic clutter.

In the setup of **Table 1**, the null hypotheses need not be point nulls such as H_0: $\delta = 0$. They can also be directional nulls (such as H_0: $\delta \leq 0$) or even interval nulls such as H_0: $\delta \leq -0.20$ or $\delta \geq +0.20$, as is used in bioequivalence studies (Berger and Hsu, 1996). Alternatively, one can specify an 'effect size' measure θ (see, e.g., Cohen, 1992) and test a null hypothesis of the form H_0: $\theta \leq 0.20$; rejection would ensure that the effect size is meaningful rather than simply nonzero. Since much of the criticism of hypothesis testing in the social sciences literature is aimed at point null hypotheses, use of more general null hypotheses removes much of the criticism concerning significance testing, and makes MCPs relevant for social science research.

The FWER is defined as $\text{FWER} = \text{P}(V > 0)$. With more technical precision, $\text{FWER} = \sup_{\Theta} \text{P}(V > 0)$, where Θ is a set of relevant nuisance parameters. In words, the FWER is the (maximum) probability of making an erroneous claim for the prespecified family of inferences.

The FDR is defined loosely as $\text{FDR} = \text{E}(V/R)$. However, since R can be zero, the definition must be modified so that the ratio V/R will be counted as zero in the expectation calculation. And again, with more technical precision, $\text{FDR} = \sup_{\Theta} \text{E}(V/R)$, where Θ is a set of relevant nuisance parameters. In loose words, the FDR is the percentage of erroneous claims, among all claims that are made in a study.

Both the FWER and FDR are quantities that the researcher would like to control at a low level, typically 0.05. If $\text{FWER} = 0.05$ for a given procedure, then the researcher may be confident that all significances are in fact real, because only one in 20 studies will result in one or more incorrectly significant results. If $\text{FDR} = 0.05$ for a given procedure, then the researcher cannot be confident that all discovered significances are in fact real, but can be loosely confident that 95% of them are real and 5% are errors. The FDR criterion is looser than the FWER criterion because it allows false positives, hence FDR-controlling methods are usually less conservative than FWER-controlling methods.

To illustrate the difference between FWER and FDR more specifically, consider a hypothetical study in which there are $k = 100$ hypotheses tested, $k_0 = 60$ of which are true nulls and $k_1 = 40$ of which are true alternatives. Suppose also that the true alternatives have large effect sizes and large sample sizes, so that statistical significance is virtually assured, that the tests are independent, and that the tests are all performed at the usual 0.05 significance level, unadjusted for multiplicity. After the study, there will be a random number V of significances among the $k_0 = 60$ true nulls; here V is a binomial random variable with 60 trials and probability 0.05 of 'success.' Hence, $\text{FWER} = \text{P}(V > 0) = 1 - \text{P}(V = 0) = 1 - \{60!/(60! \times 0!)\}\ 0.05^0\ 0.95^{60-0} = 0.954$. In other words, there is a 95.4% chance of finding a false significance in this hypothetical study.

On the other hand, $\text{FDR} = \text{E}(V/R) = \text{E}\{V/(V+40)\} = \sum_{v=0}^{60} \frac{v}{v+40} \times \frac{60!}{(60-v)!v!} 0.05^v. \times 95^{60-v} = 0.068$. In other words, the expected ratio of false significances to total significances is 0.068 for this study.

To control either the FWER or the FDR at the 0.05 level in this hypothetical study, one can use a critical p-value threshold lower than the standard 0.05. To control FWER, one can use a low threshold $1 - 0.95^{1/60} = 0.000854$. But the FDR is already close to 0.05, so not nearly as much adjustment is needed: Direct evaluation of the FDR expression above shows that 0.036 works in this case to control the FDR at the level 0.05. (These threshold calculations are for illustrative purposes only; in practice one cannot use them because the number of true null, k_0 is unknown, and because it is unlikely that all alternatives will be highly significant.)

FWER-Controlling Methods

A method is said to control FWER at level α if $\text{FWER} \leq \alpha$ whenever that method is used. Methods that do not control the FWER can have $\text{FWER} > \alpha$ for certain parameter configurations.

Some notation: The null hypotheses are H_i, with corresponding p-values p_i, $i = 1,\ldots,k$. The ordered p-values are $p_{(1)} \leq p_{(2)} \leq \ldots \leq p_{(k)}$, corresponding to respective hypotheses $H_{(1)}$, $H_{(2)}$, … ,$H_{(k)}$. The simplest FWER-controlling method is the Bonferroni method, where one rejects all $H_{(i)}$ for which $p_{(i)} \leq \alpha/k$; here α is the desired FWER. Note that the Bonferroni method does not require the ordered p-values, but the stepwise methods defined below do.

Most FWER-controlling methods are quite similar to the Bonferroni method in their extreme dependence on k, with larger k making the procedure more conservative. However, there are several methods for improving the power, while retaining FWER control. A good general reference for the methods given below is Westfall et al. (2011).

Stepwise and testing methods: These methods involve testing the hypotheses sequentially, in order of the p-values. The simplest and most robust of these is Holm's method, where the hypotheses are tested in step-down fashion, from most significant least. If $p_{(1)} \leq \alpha/k$, then $H_{(1)}$ is rejected and the testing continues, otherwise the testing stops. At the second step, if $p_{(2)} \leq \alpha/(k-1)$, then $H_{(2)}$ is rejected and the testing continues, otherwise the testing stops. Testing continues in this fashion until a stop, or until all hypotheses have been rejected. It is clear that the method uniformly improves over Bonferroni, because the denominators $k-j$ of the critical values $\alpha/(k-j)$ are smaller than the denominator k of the Bonferroni method.

There are step-up variations as well, and these typically require assumptions concerning the correlation structure. The simplest and most famous is Hochberg's method, defined as follows: If $p_{(k)} \leq \alpha/1$, then reject all of $H_{(1)},\ldots,H_{(k)}$ and stop. Otherwise 'accept' $H_{(k)}$ and continue testing. At the second step, if $p_{(k-1)} \leq \alpha/2$, then reject all of $H_{(1)},\ldots,H_{(k-1)}$ and stop. Otherwise 'accept' $H_{(k-1)}$ and continue testing. Testing

continues in this fashion until a stop, or until no hypotheses can be rejected.

Hochberg's step-up testing method always finds the same significances as Holm's method, but sometimes more. The improved power comes at a price though: The method can fail to control the FWER in cases of negatively correlated p-values (Westfall et al., 2001).

Closed and logically constrained testing methods: Holm's method is a special case of what are called closed testing procedures; these require enumeration and testing of all subset intersection hypotheses. These methods can be computationally demanding in general because $2^k - 1$ intersection tests are needed, although there are shortcuts in many cases, Holm's method being an example. In cases where the hypotheses satisfy logical constraints, as is the case with all pairwise comparisons, the denominators of the critical values are substantially smaller than those of Holm's method, leading to more power.

Using correlations: Holm's method and its variants do not utilize the correlation structure among the p-values. When there are correlations, these methods can be improved uniformly when such correlations are incorporated into the testing method. Implicitly, the denominators of the critical values are smaller depending on the correlation structure. The higher the correlation, the greater the reduction in the denominator. Tukey's method and Dunnett's method are classical examples of such correlation-utilizing methods (Westfall et al., 2011).

Using non-normal distributional characteristics: When data are highly discrete, the tests involving the more discrete data can be downweighted so as not to contribute to the multiplicity adjustment, further improving power (Westfall and Young, 1993).

The Benjamini–Hochberg FDR-Controlling Method

Like FWER-controlling methods, a method is said to control FDR at level α if FDR $\leq \alpha$ when that method is used. Methods that do not control the FDR can have FDR $> \alpha$ for certain plausible parameter configurations. The most commonly used FDR-controlling method is the Benjamini–Hochberg (B–H) method, a step-up method defined as follows:

- If $p_{(k)} \leq k\alpha/k$, then reject all of $H_{(1)},\ldots,H_{(k)}$ and stop. Else 'accept' $H_{(k)}$ and continue testing.
- If $p_{(k-1)} \leq (k-1)\alpha/k$, then reject all of $H_{(1)},\ldots,H_{(k-1)}$ and stop. Else 'accept' $H_{(k-1)}$ and continue testing.
- If $p_{(k-2)} \leq (k-2)\alpha/k$, then reject all of $H_{(1)},\ldots,H_{(k-2)}$ and stop. Else 'accept' $H_{(k-2)}$ and continue testing.
- … Continue in this fashion until a stop or until no hypotheses are rejected.

The B–H method is similar to Hochberg's FWER-controlling method in that it is a step-up method, and in that it can fail in cases of negatively dependent p-values. But what is most interesting is the comparison of the critical values: Hocherg's method compares $p_{(j)}$ to $\alpha/(k-j+1)$, whereas the B–H method compares $p_{(j)}$ to $\alpha/(k/j)$. Simple math shows that $\alpha/(k/j) \geq \alpha/(k-j+1)$, proving that the B–H method always finds the same significances as the Hochberg method, but possibly more. A more telling story is shown in **Figure 1**. With $k = 100$ tests, the thresholds to be exceeded by the Hochberg method are clearly much smaller than those of the B–H method. It is also apparent that the Hochberg thresholds are similar to the simple Bonferroni 0.05/100 threshold for all but the largest p-values, whereas the B–H thresholds linearly move from the Bonferroni threshold 0.05/100 to the unadjusted threshold 0.05.

Figure 1 Critical p-value thresholds for Hochberg's method (+'s) and the B–H method (o's) when there are $k = 100$ tests. The Bonferroni threshold 0.05/100 is shown as a dashed line and the unadjusted threshold 0.05 is shown as a dotted line. R code is `t = 1:100`; BHt = 0.05/(100/t − 1); Ht = 0.05/(100 − t + 1); plot(t, BHt, xlab = "Ordered p-value j", ylab = "threshold"); abline(h = 0.05/100, lty = 2); abline(h = 0.05, lty = 3).

There are many variants and extensions of the B–H method; Efron (2010) is an excellent reference.

Adjusted p-values

Adjusted p-values are interpreted just like ordinary p-values in that you simply compare them to 0.05 (or other desired thresholds). The simplest case is the standard Bonferroni method: Significances occur when $p_j \leq 0.05/k$; or equivalently, when $kp_j \leq 0.05$. Thus, kp_j is the Bonferroni-adjusted p-value. Usually, this number is truncated at 1.0, since probabilities can never be greater than 1.0, leading to the definition $\min(kp_j, 1.0)$. For stepwise and correlation-utilizing testing methods the formulas for the adjusted p-values are more complex, but the logic is similar; see Westfall et al. (2011).

If the adjusted p-values are obtained using an FWER-controlling method, then all adjusted p-values ≤ 0.05 correspond to significances at the FWER = 0.05 level. If the adjusted p-values are obtained using an FDR-controlling method, then all adjusted p-values ≤ 0.05 correspond to significances at the FDR = 0.05 level.

Software for performing the analyses above are readily available in the R and SAS software. Both of these packages provide adjusted p-values, in R they are in p.adjust and

elsewhere, in SAS they are in PROC MULTTEST and elsewhere.

The code in Table 2 illustrates how to calculate adjusted p-values for a collection of 100 tests, using both the Hochberg FWER-controlling and B–H FDR-controlling methods. Both the p.adjust function in R and the PROC MULTTEST procedure in SAS require the user to input a collection of raw (unadjusted) p-values, obtained by any means whatsoever. Using R, the code is as shown in Table 2.

Figure 2 shows a comparison of the adjusted p-values obtained using the code in Table 2. Any p-value below the 0.05 threshold indicates significance using the chosen criterion. The most significances (23 in the simulation) are obtained using the raw, unadjusted p-values, but these offer no control over FWER or FDR. Fewer significances (10 in the simulation) are found using the B–H-adjusted p-values; for these the interpretation is 'roughly 5% of the 10 significances are Type I errors.' The fewest significances (four in the simulation) are found using the Hochberg-adjusted p-values; for these the interpretation is that none of the four are Type I errors, because a Type I error will occur in only 1 in 20 studies, and this particular study is not likely to be one of those.

Table 2 Code for obtaining adjusted p-values in R

```
set.seed(12345)  ## to ensure replicability
pvals =          ## Runif is null case, runif^2
  runif(100)^2     provides smaller pvals as under
                 ## the alternative. In practice
                    the pvals come from the study.
                 hoch.adjp = p.adjust(pvals,
                   method = "hochberg") bh.adjp
                   = p.adjust(pvals,
                   method = "BH")
```

Figure 2 Unadjusted p-values (o's), B–H-adjusted p-values (+'s), and Hochberg-adjusted p-values (X's). Any p-value below the horizontal line at 0.05 indicates significance using the selected Type I error control criterion. R code is plot(sort(pvals), ylim = c(0,1), ylab = "p-value", xlab = "ordered test, j"); points(sort(bh.adjp), pch = "+"); points(sort(hoch.adjp), pch = "x"); abline(h = 0.05).

Bayesian Methods

A rather different approach to multiplicity adjustment is found in the Bayesian paradigm, wherein all inferences, whether individual or multiple, about parameters θ_j are obtained from posterior distribution of the vector $\boldsymbol{\theta} = (\theta_1, \theta_2, \ldots, \theta_k)$, given the data $\boldsymbol{\gamma} = (\gamma_1, \gamma_2, \ldots, \gamma_n)$. The posterior distribution is given by $p(\boldsymbol{\theta}|\boldsymbol{\gamma}) = c \times L(\boldsymbol{\theta}|\boldsymbol{\gamma}) \times p(\boldsymbol{\theta})$, where $L(\boldsymbol{\theta}|\boldsymbol{\gamma})$ is the likelihood function, $p(\boldsymbol{\theta})$ is the researcher's prior, and c is a constant of proportionality to ensure integration to 1.0. Modern software allows researchers to sample random vectors $\boldsymbol{\theta}^*$ from $p(\boldsymbol{\theta}|\boldsymbol{\gamma})$ with relative ease; with enough samples, accurate posterior inferences are obtained.

Classical MCPs have been historically disparaged by the Bayesians; however, influential Bayesian statisticians have recently modified their stances. Berger (1985) stated that multiple testing is no more difficult than individual testing, while Berger (2012) stated that failure to adjust for multiplicity is a reason for nonreplicability. Berry (1987) dismissed MC because of their inconsistency with the likelihood principle, but more recently commented "I no longer think Bayesians have an inside track. Multiple comparisons is an example" (reported in Stangl et al., 2012).

As it turns out, there are many correspondences between Bayesian and frequentist MCPs, and the modern approach is to look for methods that have reasonable credibility from both standpoints. One step in this direction was given by Westfall et al. (1997), who showed how the Bonferroni-adjusted p-value kp_j corresponds to the Bayesian posterior probability $\mathrm{P}(\theta_j = 0|\boldsymbol{\gamma})$. The result is obtained by comparing posterior inferences under the case (1) the priors $\mathrm{P}(\theta_j = 0)$ are all set at 0.5, versus the case (2) the prior $\mathrm{P}(\theta_j = 0, \text{all } j)$ is set at 0.5. The comparison of the posterior probabilities $\mathrm{P}(\theta_j = 0|\boldsymbol{\gamma})$ under cases (1) and (2) loosely corresponds to the comparison of the raw p_j with the Bonferroni-adjusted kp_j. An implication is that Bonferroni-style adjustment is reasonable when the joint null hypothesis is plausible, as is the case, for example, in experiments involving extrasensory perception.

A more direct correspondence, one that does not consider adjustments to the prior distribution, is found between FDR-adjusted p-values and Bayesian posterior probabilities (Efron et al., 2001), although the result is not fully Bayesian. More direct correspondences are obtained using a variant of FDR-adjusted p-values called the 'local false discovery rate' (Efron, 2010).

Other correspondences are detailed by Westfall (2005), who noted that classical (e.g., Tukey and Dunnett) simultaneous confidence intervals for parameters θ_j are identical to simultaneous Bayes intervals when using standard vague multivariate priors. Further, as noted by Westfall (1988), Bayesian simultaneous probabilities of rankings of parameters θ_j share similarities to frequentist methods in their conservativeness. For example, if one wants to know whether θ_a is the largest of the collection $\{\theta_j\}$, the Bayesian joint probability $\mathrm{P}(\theta_a \geq \max\{\theta_j\}|\boldsymbol{\gamma})$ will typically be much less than the probability for any individual comparison $\mathrm{P}(\theta_a \geq \theta_j|\boldsymbol{\gamma})$, corresponding loosely to the difference between the more conservative simultaneous (adjusted) inference for the parameters θ_j versus the less conservative individual (unadjusted) inferences for the θ_j found in

frequentist statistics. Westfall et al. (2011: Chapter 20) provide software and examples to obtain these and other Bayesian style inferences.

But what distinguishes Bayesian approaches to multiplicity adjustment most from frequentist methods is that, when a hierarchical prior is used, the parameter estimates themselves are adjusted according to the chosen family of k inferences. An example is shown in Gelman et al. (2013, pp. 109–110), wherein the parameters θ_j are binomial tumor development probabilities for rodents in treatment group j. Using a hierarchical prior $\theta_j \mid \alpha, \beta \sim \text{Beta}(\alpha, \beta)$; $p(\alpha, \beta) \propto (\alpha+\beta)^{-5/2}$, they derive a posterior distribution $\{\theta_j|\gamma, \alpha, \beta\} \sim \text{Beta}(\alpha + f_j, \beta + n_j - f_j)$, where f_j and n_j are the tumor frequency and sample size in group j, respectively. The parameters α and β likewise have a posterior distribution given γ; this distribution characterizes the mean and variance in the θ_j that is supported by the data γ. The mean is $\alpha/(\alpha+\beta)$ and the variance is roughly proportional to $1/(\alpha+\beta)$. Thus, in cases where the θ_j are nearly identical, $(\alpha+\beta)$ is large.

For example, suppose $\alpha = 300$ and $\beta = 700$ are supported by the data, suggesting a mean θ_j of 0.300 and a small variance. In this case the raw data $f_j/n_j = 30/50 = 0.600$ are 'shrunken' to a posterior probability estimate around $(300+30)/(1000+50) = 0.314$. On the other hand, with large variance and the same mean, say $\alpha = 0.3$ and $\beta = 0.7$, there is little posterior shrinkage: The same raw data $f_j/n_j = 30/50 = 0.600$ yield a nearly identical posterior estimate around $(0.3+30)/(1+50) = 0.594$. Thus the Bayesian solution to the problem of 'cherry picking' extreme results is to shrink the extreme estimates toward the overall mean, with shrinkage dependent upon the (estimated) true variation in the parameters.

While shrinkage is an attractive solution to the MC problem, it is not a panacea, because there are strong prior assumptions. Hierarchical priors assume that all parameters are different. While this may seem reasonable on its face, there are compelling reasons to consider mixture priors that place a large (say, 50% or more) probability on equality of parameters (or near equality as in Berger and Delampady, 1987) with the remaining prior density continuous and more or less uniform. Such priors are called 'spike and slab' priors, often used for variable selection in regression (Scheipl et al., 2012). In the MCP arena, such priors also can be used to identify homogeneous subsets of means in ANOVA (Gopalan and Berry, 1998). It turns out that posterior inference is highly dependent upon whether there is a spike and slab versus smooth prior: In the unadjusted inference case, Berger and Sellke (1987) find that the posterior probability of a null hypothesis can be more than 0.30 when a p-value is 0.05 and spike and slab priors are used, whereas Casella and Berger (1987) find that the posterior probability of a null is less than 0.05, given a p-value of 0.05, when smooth priors are used. In the multiple inference case, the differences are more extreme because of further dependence on multivariate prior probabilities for joint nulls (Westfall et al., 1997; Gönen et al., 2003). Thus, prespecification and justification of the family of inferences *and* their joint prior is extremely important in Bayesian MCPs, as the posterior conclusions are highly nonrobust to alternative prior specifications.

Conclusion

There are excellent solutions to the multiplicity problem, on both sides of the Bayes/frequentist fence. However, in all cases the methods require prespecification of the family and analysis methods (including priors in the Bayesian case), with solid justification, before data collection. This is best accomplished via pre-registration. Any post hoc construction to solve the MC problem is flawed because there is no clear definition of the family (and of the prior on the family, in the Bayesian case) over which the inferences are to be performed. In the absence of pre-registration, it seems to me that the best solution is to go back to the basics of science, confirming the results not by applying post hoc multiplicity corrections, but instead by replicating the study in fresh contexts.

Abstract

Imputation, that is, filling in a value for each missing datum, is a common approach to handling missing data that has many desirable properties. For example, it allows the application of standard analytic methods that have been developed for complete data sets. Moreover, in the context of the production of public-use data sets, it allows the data producer to incorporate information that might not be available to secondary users of the data, and it ensures consistency of analyses across secondary users since the missing-data problem is fixed in the same way for all of the analyses. Multiple imputation retains the advantages of imputing once for each missing datum, and it provides the added advantage of reflecting the uncertainty about the missing values so that statistically valid analyses may be carried out. With multiple imputation, the missing values are filled in two or more times using an appropriate distribution for the missing values, resulting in two or more completed data sets. The standard complete-data analysis is then applied to each completed data set, and the resulting analyses are combined in a simple way to yield the final inference. Multiple imputation has a Bayesian motivation, but it has been shown to have good frequentist properties.

Missing data are ubiquitous in social science research. For example, they occur in a survey on people's attitudes when some people do not respond to all of the survey questions, or in a longitudinal survey when some people drop out. A common technique for handling missing data is to impute, that is, fill in, a value for each missing datum. This results in a completed data set, so that standard methods that have been developed for analyzing complete data can be applied immediately (*see* Nonsampling Errors; Missing Data).

Imputation has other advantages in the context of the production of a data set for general use, such as a public-use file. For example, the data producer can use specialized knowledge about the reasons for missing data, including confidential information that cannot be released to the public, to create the imputations; and imputation by the data producer fixes the missing data problem in the same way for all users, so that consistency of analyses across users is ensured. When the missing-data problem is left to the user, the knowledge of the data producer can fail to be incorporated, analyses are not typically consistent across users, and all users expend resources addressing the missing-data problem.

Although imputing just one value for each missing datum satisfies critical data-processing objectives and can incorporate knowledge from the data producer, it fails to achieve statistical validity for the resulting inferences based on the completed data. Specifically, for validity, the resulting estimates based on the data completed by imputation should be approximately unbiased for their population estimands, confidence intervals should attain at least their nominal coverages, and tests of null hypotheses should not reject true null hypotheses more frequently than their nominal levels. But a single imputed value cannot reflect any of the uncertainty about the true underlying value, and so analyses that treat imputed values just like observed values systematically underestimate uncertainty. Thus, using standard complete-data techniques will result in standard error estimates that are too small, confidence intervals that undercover, and p-values that are too significant; even if the modeling for imputation is carried out carefully. For example, large-sample results by Rubin and Schenker (1986) show that for simple situations with 30% of the data missing, single imputation under the correct model followed by the standard complete-data analysis results in nominal 90% confidence intervals having actual coverages below 80%. The inaccuracy of nominal levels is even more extreme in multiparameter problems (Rubin, 1987: Chapter 4), where nominal 5% tests can easily have rejection rates of 50% or more when the null hypothesis is true.

Multiple imputation (Rubin, 1987) retains the advantages of single imputation while allowing the data analyst to obtain valid assessments of uncertainty. The key idea is to impute two or more times for the missing data using independent draws of the missing values from a distribution that is appropriate under the posited assumptions about the data and the mechanism that creates missing data, resulting in two or more completed data sets, each of which is analyzed using the same standard complete-data method. The analyses are then combined in a simple generic way that reflects the extra uncertainty due to having imputed rather than actual data. Multiple imputations can also be created under several different models to display sensitivity to the choice of missing-data model.

Theoretical Motivation for Multiple Imputation

The theoretical motivation for multiple imputation is Bayesian (*see* Bayesian Statistics), although the procedure has excellent properties from a frequentist perspective. Formally, let Q be the population quantity of interest, and suppose the data can be

partitioned into the observed values $\mathbf{X_{obs}}$ and the missing values $\mathbf{X_{mis}}$. If $\mathbf{X_{mis}}$ had been observed, inferences for Q would have been based on the complete-data posterior density $p(Q|\mathbf{X_{obs}}, \mathbf{X_{mis}})$. Because $\mathbf{X_{mis}}$ is not observed, inferences are based on the actual posterior density $p(Q|\mathbf{X_{obs}})$, which can be expressed as

$$p(Q|\mathbf{X_{obs}}) = \int p(Q|\mathbf{X_{obs}}, \mathbf{X_{mis}})p(\mathbf{X_{mis}}|\mathbf{X_{obs}})\mathrm{d}\mathbf{X_{mis}} \quad [1]$$

Equation [1] shows that the actual posterior density of Q can be obtained by averaging the complete-data posterior density over the posterior predictive distribution of $\mathbf{X_{mis}}$. In principle, the set of multiple imputations under one model are repeated independent draws from $p(\mathbf{X_{mis}}|\mathbf{X_{obs}})$. Thus, multiple imputation allows the data analyst to approximate eqn [1] by separately analyzing each data set completed by imputation and then combining the results of the separate analyses.

Analyzing a Multiply-Imputed Data Set

The exact computation of the posterior distribution (eqn [1]) by simulation would require that an infinite number of values of $\mathbf{X_{mis}}$ be drawn from $p(\mathbf{X_{mis}}|\mathbf{X_{obs}})$. Fortunately, simple approximations work very well in most practical situations with only three to five imputations.

Inferences for Scalar *Q*

Suppose, as is typically true in the social and behavioral sciences, that if the data were complete, inferences for Q would be based on a point estimate $\hat{Q}$, an associated variance/covariance estimate U, and a normal reference distribution. When data are missing and there are M sets of imputations for the missing data, the result is M sets of complete-data statistics, say, $\hat{Q}_m$ and U_m, $m = 1, \ldots, M$.

The following procedure is useful for drawing inferences about Q from the multiply imputed data (Rubin, 1987; Rubin and Schenker, 1986). The point estimate of Q is the average of the M completed-data estimates,

$$\overline{Q} = \sum_{m-1}^{M} \hat{Q}_m \Big/ M$$

and the associated variance estimate is

$$T = \overline{U} + \left(1 + M^{-1}\right)B$$

where $\overline{U} = \sum_{m-1}^{M} U_m/M$ is the average within-imputation variance, and $B = \sum_{m-1}^{M}(\hat{Q}_m - \overline{Q})^2/(M-1)$ is the between-imputation variance (cf the usual analysis of variance breakdown in 42318). The approximate reference distribution for interval estimates and significance tests is a t distribution with degrees of freedom

$$\nu = \left(\nu_m^{-1} + \hat{\nu}_{obs}^{-1}\right)^{-1}$$

where $\nu_m = (M-1)\hat{\gamma}^{-2}$, $\hat{\nu}_{obs} = \nu_{com}(1-\hat{\gamma})(\nu_{com}+1)/(\nu_{com}+3)$, $\hat{\gamma} = (1+M^{-1})B/T$ is the approximate Bayesian fraction of missing information, and ν_{com} is the complete-data degrees of freedom (see Barnard and Rubin, 1999 for the derivation).

Significance Tests for Multicomponent Estimands

Multivariate analogues of the expressions given in the previous section for scalar Q are summarized by Rubin (1987: Section 3.4). Methods also exist for likelihood-ratio testing when the available information consists of point estimates and evaluations of the complete-data log-likelihood-ratio statistic as a function of these estimates and the completed data.

With large data sets and large models, such as in the common situation of a multi-way contingency table, the complete-data analysis might produce only a test statistic and no estimates (cf Multivariate Analysis: Discrete Variables (Overview)). Rubin (1987: Section 3.5) provided initial methods for situations with such limited information, and improved methods exist that require only the M complete-data χ^2 statistics (or equivalently the M complete-data p-values). These methods, however, are less accurate than methods that use the completed-data estimates.

Creating Multiple Imputations

Ideally, multiple imputations are M independent random draws from the posterior predictive distribution of $\mathbf{X_{mis}}$ under appropriate Bayesian modeling assumptions. Such imputations are called repeated imputations by Rubin (1987: Chapter 3). In practice, approximations often are used and work well.

Modeling Issues

An initial modeling issue in creating imputations is that the predictive distribution for the missing values should be conditional on all observed values. This consideration is particularly important in the context of a public-use database. Leaving a variable out of the imputation model is equivalent to assuming that the variable is not associated with the variables being imputed, conditionally given all other variables in the model; imputing under this assumption can result in biases in subsequent analyses, with estimated parameters representing conditional association pulled toward zero. Because it is not known which analyses will be carried out by subsequent users of a public-use database, ideally it is best not to leave any variables out of the imputation model. Thus, it is desirable to condition imputations on as many variables as possible and to use subject-matter knowledge to help select those variables that are likely to be used together in subsequent complete-data analyses, as by Clogg et al. (1991).

Imputation procedures can be based on explicit models or implicit models, or even combinations (see, e.g., Rubin, 1987: Chapter 5; Rubin and Schenker, 1991). An example of a procedure based on an explicit model is stochastic normal regression imputation, where imputations for missing values are created by adding normally distributed errors to predicted values obtained from a least-squares regression fit. A common procedure based on implicit models is hot-deck imputation, which replaces the missing values for an incomplete case by the values from a matching complete case, where the matching is carried out with respect to variables that are observed for both the incomplete case and complete cases.

The model underlying an imputation procedure, whether explicit or implicit, can be based on the assumption that the reasons for missing data are either ignorable or nonignorable (see Rubin, 1976; Missing Data). The distinction between an ignorable and a nonignorable model can be illustrated by a simple example with two variables, X and Y, where X is observed for all cases whereas Y is sometimes missing. Ignorable models assert that a case with Y missing is only randomly different from a complete case having the same value of X. Nonignorable models assert that there are systematic differences between an incomplete case and a complete case even if they have identical X-values. An important issue with nonignorable models is that, because the missing values cannot be observed, there is no direct evidence in the data to address the assumption of nonignorability. It can be important, therefore, to consider several alternative models and to explore sensitivity of resulting inferences to the choice of model. In current practice, almost all imputation models are ignorable; limited experience suggests that in major surveys with limited amounts of missing data and careful design, ignorable models are satisfactory for most analyses (see, e.g., Rubin et al., 1995).

Incorporating Proper Variability

Multiple imputation procedures that incorporate appropriate variability across the M sets of imputations within a model are called 'proper' by Rubin (1987: Chapter 4) where precise conditions for a method to be proper are also given; also see Meng (1994) and Rubin (1996). Because, by definition, proper methods reflect sampling variability correctly, inferences based on the multiply-imputed data are valid from the standard repeated-sampling (i.e., design-based) frequentist perspective.

One important principle related to incorporating appropriate variability is that imputations should be random draws rather than best predictions. Imputing best predictions can lead to distorted estimates of quantities that are not linear in the data, such as measures of variability and correlation, and it generally results in severe underestimation of uncertainty and therefore invalid inferences.

For imputations to be proper, the variability due to estimating the model must be reflected along with the variability of data values given the estimated model. For this purpose, a two-stage procedure is often useful. Fixing parameters at a point estimate (e.g., the maximum likelihood estimate), across the M imputations and drawing $\mathbf{X}_{\mathbf{mis}}$ from this distribution-generally leads to inferences based on the multiply-imputed data that are too sharp. First drawing the parameters from their joint posterior distributions is preferable.

The two-stage paradigm can be followed in the context of nonparametric methods such as hot-deck imputation as well as in the context of parametric models with formal posterior distributions for parameters. The simple hot-deck procedure that randomly draws imputations for incomplete cases from matching complete cases is not proper because it ignores the sampling variability due to the fact that the population distribution of complete cases is not known but rather is estimated from the complete cases in the sample. Rubin and Schenker (1986, 1991) discussed the use of the bootstrap (*see* Resampling Methods of Estimation) to make the hot-deck procedure proper, and called the resulting procedure the 'approximate Bayesian bootstrap.' The two-stage procedure first draws a bootstrap sample from the complete cases and then draws imputations randomly from the bootstrap sample. Thus, the bootstrap sampling from the complete cases before drawing imputations is a nonparametric analogue of drawing values of the parameters of the imputation model from their posterior distribution before imputing conditionally upon the drawn parameter values. Heitjan and Little (1991) illustrated the use of bootstrap sampling to create proper imputations with a parametric model.

Choice of *M*

The choice of M involves a tradeoff between simulating more accurately the posterior distribution and using a smaller amount of computing and storage. The effect of the value of M on accuracy depends on the fraction of information about the estimand Q that is missing (Rubin, 1987: Chapters 3, 4). With ignorable missing data and just one variable, the fraction of missing information is simply the fraction of data values that are missing. When there are several variables and ignorable missing data, the fraction of missing information is often smaller than the fraction of cases that are incomplete because of the ability to predict missing values from observed values; this is often not true with nonignorable missing data, however.

For the moderate fractions of missing information ($<30\%$) that occur with most analyses of data from most large surveys, Rubin (1987: Chapter 4) showed that a small number of imputations (say, $M = 3$ or 4) results in nearly fully efficient estimates of Q. In addition, if proper multiple imputations are created, then a substantial body of work suggests that the resulting inferences generally have close to their nominal coverages or significance levels, even when the number of imputations is moderate (Clogg et al., 1991; Heitjan and Little, 1991; Rubin and Schenker, 1986; additional publications cited by Rubin, 1996).

Use of Iterative Simulation Techniques

Recent developments in iterative simulation, such as data augmentation (Tanner and Wong, 1987) and Gibbs sampling (Gelfand and Smith, 1990), can facilitate the creation of multiple imputations in complicated parametric models (*see* Markov Chain Monte Carlo Methods). Consider a joint model for $\mathbf{X}_{\mathbf{obs}}$ and $\mathbf{X}_{\mathbf{mis}}$ governed by a parameter, say θ. The data augmentation (Gibbs sampling) procedure that results in draws from the posterior distribution of θ produces multiple imputations as well. (Schafer, 1997) developed algorithms that use iterative simulation techniques to multiply impute data when there are arbitrary patterns of missing data and the missing-data mechanism is ignorable.

Some Recent Applications of Multiple Imputation in Social-Science Research

To illustrate settings in which multiple imputation can be useful, brief descriptions of several recent applications of multiple imputation to social-science research are now given. References to many other examples are provided by Rubin (1996).

Multiple Imputation to Achieve Comparability of Industry and Occupation Codes over Time

The first large-scale application of multiple imputation for public-use data involved employment information from the decennial census. In each census, such information is obtained from individuals in the form of open-ended descriptions of occupations. These descriptions are then coded into hundreds of industries and occupations, using procedures devised by the Census Bureau. Major changes in the procedures for the 1980 census resulted in public-use databases from the 1980 census with industry and occupation codes that were not directly comparable to those on public-use databases from previous censuses, in particular, the 1970 census. This lack of comparability made it difficult to study such topics as occupation mobility and labor force shifts by demographic characteristics.

Because of the size of the 1970 public-use databases (about 1.6 million cases) and the inaccessibility of the original descriptions of occupations, which were stored away on microfilm, it would have been prohibitively expensive to recode the 1970 data according to the 1980 scheme. There existed, however, a smaller (about 127 000 cases) double-coded sample from the 1970 census, that is, a sample with both 1980 and 1970 occupation codes, that had been created for other purposes. Based on Bayesian models estimated from the double-coded sample, five sets of 1980 codes were imputed for the 1970 public-use database as outlined by Clogg et al. (1991). Simulations described by Rubin and Schenker (1987) support the validity of multiple-imputation inferences in this application. Finally, analyses described by Schenker et al. (1993) demonstrated potential gains in efficiency from basing analyses on the multiply imputed public-use sample rather than on the smaller double-coded sample, even though the actual 1980 codes are known on the latter and unknown on the former.

Multiple Imputation for Missing Data in a National Health Survey

The National Health and Nutrition Examination Survey (NHANES) is conducted by the National Center for Health Statistics (NCHS) to assess the health and nutritional status of the United States population and important subgroups. The data from NHANES are obtained through household interviews and through standardized physical examinations. NCHS has recently made available a database from the third NHANES, in which multiple imputation based on complicated multivariate models and iterative simulation techniques was used to handle missing data. This multiple-imputation project is significant because it demonstrates the feasibility of generating proper multiple imputations for a public-use sample obtained by a complex survey design with many observations and variables, varying rates of missingness on key variables of interest, and various patterns of nonresponse.

Documentation available with the database contains descriptions of the models and procedures used to multiply impute data for the third NHANES, as well as descriptions and examples of how to analyze the multiply-imputed data. Earlier work on the project is summarized by Schafer et al. (1996). In particular, a simulation study of the validity of multiple-imputation interval estimates was conducted based on a hypothetical population constructed from data from the third NHANES as well as earlier versions of NHANES. Results indicated that the imputation procedures were successful in creating valid design-based repeated-sampling inferences.

Multiple Imputation in a Study of Drinking Behavior with Follow-up for Nonresponse

The Normative Aging Study was a longitudinal study of community-dwelling men conducted by the Veterans Administration in Boston. In a survey on drinking behavior conducted as part of this study, a large fraction of the men surveyed provided essentially complete information, whereas for a smaller fraction, there was background information available but no information on drinking behavior. Because drinking behavior is a sensitive subject, there was concern that such nonresponse might be nonignorable.

In a follow-up survey, information on drinking behavior was obtained from about one-third of the initial nonrespondents. Glynn et al. (1993) multiply imputed data on drinking for the roughly two-thirds of the initial nonrespondents who remained, under the assumption that, in the stratum of initial nonrespondents, given the follow-up information as well as the background information that had been collected previously, nonresponse was now ignorable. It was found that inferences about the effect of retirement status on drinking behavior (adjusting for age) were very sensitive to whether the multiply-imputed data or only the data for the initial respondents were used.

A Contest: Multiply Imputing the Consumer Expenditure Survey

Raghunathan and Rubin (1997) describe a simulation study to examine the frequentist properties of various methods of generating multiple imputations that was funded by the United States Bureau of Labor Statistics (BLS). The simulation study used real data from the Consumer Expenditure Survey (CES), which is the most detailed source of expenditures, income, and demographics collected by the US government. The objective of the simulation study was to compare frequentist performance of imputation-generation methods that differed by whether they fully accounted for parameter uncertainty and/or whether they conditioned on all observed variables. The recommended approach in the multiple-imputation literature is to generate imputations that account for all sources of uncertainty and condition on all observed information. Some BLS staff questioned this recommendation, preferring to use simpler methods for generating imputations that do not account for parameter uncertainty and exclude some variables, in this case measures of expenditure, because of concerns about endogeneity.

The artificial population from which the simulation samples were drawn consisted of complete reporters from the CES. BLS staff generated 200 independent samples, each of approximate size 500 from the constructed population, then imposed an ignorable monotone missing-data mechanism on each sample, resulting in 200 incomplete samples.

Two variables in the samples had missing data: ethnicity and income. The incomplete samples were then sent to the multiple-imputation team, who were unaware of the exact nature of the missing-data mechanism, for analysis. All the variables used in the missing-data mechanism as well as some other variables were provided to the multiple-imputation team without noting which were which.

The multiple-imputation team generated five imputations for each incomplete sample under a variety of approaches: accounting for parameter uncertainty and using all variables, accounting for parameter uncertainty but excluding some variables (expenditure information), ignoring parameter uncertainty and using all variables, and ignoring parameter uncertainty and excluding some variables. The multiply-imputed samples were sent to BLS for analysis. The results were that the recommended method for generating imputations, accounting for parameter uncertainty and including all variables, produced confidence intervals that had the nominal coverage whereas all of the other methods produced intervals that undercovered, with the method that ignored parameter uncertainty and excluded expenditure information having the worst performance.

Multiple Imputation in the Survey of Consumer Finances

Kennickell (1998) reported on the use of multiple imputation for handling missing data and for disclosure limitation in the Survey of Consumer Finances (SCF). The SCF is a triennial survey conducted by the US Board of Governors of the Federal Reserve System in cooperation with the Statistics of Income Division of the Internal Revenue Service. The SCF is a major source of detailed asset, liability, and general financial information and includes over 2700 questions. The SCF is focused on the details of households' finances, and due to the sensitivity of this topic it suffers from substantial unit and item nonresponse rates. In addition, because the SCF asks many questions about monetary amounts, the skip patterns in the SCF are very complex, resulting in complicated response patterns. These factors make direct analysis of the incomplete SCF data extremely difficult for general users.

To combat the problem of missing data in the SCF, multiply-imputed versions of the SCF have been and continue to be released to the public. The SCF multiple imputations were generated using a novel variation of the Gibbs sampling algorithm that combines great modeling flexibility with computational tractability. Multiple imputation is also being used for disclosure limitation of income information in the SCF Kennickell (1997), based on ideas put forth by Rubin (1993) for protecting sensitive data by creating via imputation completely artificial populations.

Handling 'Don't Know' Survey Responses in the Slovenian Plebiscite

The Republic of Slovenia separated from Yugoslavia on 8 October 1991. One year before, Slovenians voted on independence through a plebiscite. Of eligible voters, 88.5% voted in favor of independence. To predict the results of the plebiscite, the Slovenian government inserted questions into the Slovenian Public Opinion (SPO) Survey that was conducted 4 weeks prior to the plebiscite. The SPO is a face-to-face survey of approximately 2000 voting-age Slovenians containing questions on many aspects of Slovenian life, including education and health. It has been conducted one to two times each year for the past 30 years. The plebiscite-related questions inserted into the SPO had three possible responses: 'yes,' 'no,' and 'don't know' (DK). In some surveys DK is a valid response, but in the plebiscite everyone votes either 'yes' or 'no' to the issue of independence, either by voting in person or by staying home (effectively a 'no' vote). Hence, the DK responses to the SPO survey question can be viewed as missing or masked data, masking either a 'yes' or 'no' plebiscite response.

Rubin et al. (1995) analyzed the SPO results with the goal of predicting the true percentage of voters in favor of independence. They treated the DK responses as missing data and considered ignorable and nonignorable missing-data mechanisms. Their prediction from a straightforward ignorable model was very accurate, while that from their most realistic nonignorable model was substantially far from the truth. The results are particularly interesting because the predictions were obtained before the true percentage was known and indicate that simple ignorable models can produce better answers than more complex and seemingly more plausible nonignorable models.

Conclusion

Multiple imputation is a general approach for handling the pervasive and often challenging problem of reaching statistically valid inferences from incomplete data (*see* Missing Data). It was derived from a Bayesian perspective but produces inference procedures that have excellent frequentist properties. Generating multiple imputations can be difficult, and fortunately computer software is appearing that aids in this task (see below), but analyzing a multiply-imputed data set was designed to be almost as easy as analyzing a complete data set. A multiple-imputation inference is obtained by applying a complete-data inference procedure to each of the multiple data sets completed by imputation and then combining these estimates using simple combining rules. To learn more about multiple imputation (see Rubin, 1987, 1996; Schafer, 1997).

There is currently only a limited amount of software for generating multiple imputations under multivariate complete-data models and for analyzing multiply-imputed data sets (i.e., completing the data sets, running the complete-data analyses, and combining the complete-data outputs), but the situation appears to be rapidly improving. For generating imputations, software to implement the methodology developed by Schafer (1997) has been written for the S-PLUS (Mathsoft, 2001) statistical package and is freely available on the Internet. This software includes programs for multiple imputation in the contexts of incomplete multivariate normal data, incomplete categorical data, and incomplete data under the general location model allowing both categorical and multivariate normal variables.

A revised and expanded version of this software, including facilities for easily analyzing multiply-imputed data, has been incorporated into recent release of S-PLUS. SOLAS (Statistical

Solutions, 2000), the first commercial product for multiple imputation, combines a graphical user interface and integrated environment for analyzing multiply-imputed data with flexible and efficient methods of generating imputations that exploit the computational and modeling advantages of near monotone missing-data patterns. SAS Institute is developing procedures for analyzing and generating multiply imputed data under a variety of parametric models. These procedures are expected to be available in the very near future. The web site www.multiple-imputation.com contains a fairly complete list of software for multiple imputation and serves as source for news and events associated with multiple imputation.

Abstract

Animals have evolved multiple sensory systems in order to detect and analyze different forms of energy in the environment; for example, light and sound. Perception and behavior are greatly enhanced by combining information across the senses. Although this fusion is seemingly effortless and automatic, its neural implementation is complex, as the originating sensory signals are processed in different areas of the brain with very different operating characteristics. In this article, we describe the fundamentals of multisensory integration as they apply to multiple animal species, focusing on the superior colliculus as a model system for its implementation.

One of the most important tasks the brain must perform is interpreting information relayed from its sensory organs. Both individual survival and evolutionary success depend on the speed and accuracy with which such information is processed and transformed into appropriate behaviors. This process is markedly facilitated by the brain's ability to synthesize information from different sensory systems, and the perceptual consequences of this 'multisensory integration' have intrigued philosophers of science since the time of ancient Greece. But it is only recently that we have come to understand some of the principles of multisensory integration by studying its operation at multiple levels, from its consequences on overt behavior to changes in the activity of individual neurons. These endeavors have been greatly facilitated by the study of a model system: multisensory neurons in the superior colliculus (SC). Individual SC neurons are responsive to stimuli appearing within circumscribed regions of space and produce bursts of impulses that drive the head and eye to orient toward that region. They are arranged according to their spatial sensitivity in a topographic map and collectively comprise an elegantly simple architecture in which a sudden stimulus can be registered and initiate an appropriate response toward it. An individual SC neuron can be responsive to multiple sensory modalities, and its sensory-evoked activity can be markedly enhanced or depressed, depending on the spatial and temporal relationships among the cross-modal stimuli it is responding to and the organization of its own sensitivities. These determinants of multisensory integration at the single-neuron level are closely paralleled at the level of SC-mediated overt attentive and orientation behaviors. The capacity for multisensory integration is not present in the newborn, but develops in a protracted postnatal fashion as the animal develops and gains experience with the cross-modal relationships present in the environment it will inhabit. The cross-species similarities in the principles of multisensory integration suggest a remarkable evolutionary constancy in the fundamentals of this process. Computational methods are now beginning to address whether the principles of multisensory integration detailed in the particular circuits and behaviors that have been explored represent the presence of global principles, or if the brain also utilizes specialized principles that are more closely tied to specific circuits and their associated functions.

Multiple Sensory Representations in the Brain

Across species, brain size is generally correlated with body size. Although a species' actual acumen appears more closely related to its ratio of brain mass to body mass (encephalization), this is an imperfect relationship. All species possess multiple sensory systems, and because each requires a good deal of neural circuitry to make them work, much of even the largest and most encephalized brains is devoted to their operation. Thus, the cerebral cortex, generally considered the highest stage of information processing and the seat of perception, appears to have a large portion of its area organized into a succession of higher-order sensory (and motor) processing stations. Thus far, a minimum of 32 visual, 15 auditory, and 8 somatosensory areas have been identified in the primate cortex. Somehow, though no one really knows exactly how, the coordinated activity of these multiple cortical areas across the neural expanse produces a unified perceptual experience.

That so much of the brain is devoted to sensory processing and its associated motor commands is due to the fact that survival depends on the speed and accuracy with which an organism can evaluate external events and properly react to them. Having many senses is generally better than having few, with the additional benefits outweighing the increased metabolic cost of building and maintaining the necessary underlying brain circuits. For one, different sensory modalities can substitute for one another when they are individually compromised (e.g., sight and touch substitute for vision in the dark). For another, because they sample different forms of energy, multiple senses allow the organism to simultaneously obtain different perspectives or estimates about a singular environmental event. This increases the likelihood that a given event may be correctly detected and identified because two events that appear similar to one sense may be disambiguated by another (e.g., two things that sound the same may look different). Information can be combined across the senses to produce a wholly new perspective, and in cases where each sense

imperfectly estimates a feature of the event, their combination can produce a better overall estimate of its properties.

Multisensory Integration in Perception

By synthesizing information from two or more modality-specific inputs the brain can create something that is entirely new. For example, what we think of as 'taste' is not due solely to the signals the brain receives about the food-induced chemical changes on the tongue. Rather, taste represents a synthesis of signals derived from these chemical changes (gustatory) and those from the aroma (olfactory) and texture (somatosensory) of the food. Integrating this information produces a much richer and more diverse sensory experience than would otherwise be possible. It has been known for some time that multiple sensory inputs must be bound together to produce what we experience as a 'unitary' perceptual experience, and that this binding process can have potent perceptual consequences. Yet, we are largely unaware of its actual operation. Perhaps we do not notice the process because it is the normal mode of brain operation. For example, seeing a speaker's face enhances our ability to perceive what is being said (see Sumby and Pollack, 1954), though we are not conscious that we are combining and integrating individual visual and auditory cues. Nevertheless, we might note that we concentrate particularly hard on the speaker's face in a noisy environment. The consequence is an enhancement of the brain activity underlying speech perception (e.g., see Calvert et al., 1999; Sams et al., 1991; Massaro and Stork, 1998) that is induced by the congruent visual (lip movement) and auditory (spoken words) stimuli. Indeed, visual–auditory integration in speech perception is so seamless that we are quite surprised when we experience the so-called 'McGurk effect' wherein combining the sound of one syllable or word with the lip movements of another produces a perceptual product that differs from each. For example, coupling the sound 'bows' with the lip movements used to from 'goes' leads to the perception of 'doze' or 'those.'

These sorts of cross-modal illusions are not limited to meaning, but can affect strongly perception as well. The 'ventriloquism effect' (Howard and Templeton, 1966) is a particularly powerful, yet common, illusion that alters the apparent location of an event. Voices always seem to be coming from the appropriate characters on the television screen, regardless of their location or movement. Yet, all the sounds actually originate from the same audio speakers. There are many other compelling illusions involving different senses, such as the 'parchment skin' illusion, in which the apparent texture of the skin is changed as a consequence of coupling the sensation of rubbing of the fingers with a grating sound that is played through earphones (Jousmaki and Hari, 1998). The oculogravic and somatogravic illusions (Graybiel, 1952; Clark and Graybiel, 1949) are those in which vestibular cues lead to erroneous percepts of visual orientation and body position, respectively, spatial disorientations well known to aviators for their potentially grave consequences.

These illusions are anomalies, but underscore the fact that the brain normally integrates information from different senses in order to increase its sensitivity to environmental events. In some cases, the process creates a signal that is greater than that predicted by simply summing the responses to the individual component stimuli; an excellent biological example of when the whole is greater than the sum of its parts. To make this work properly (and generally it works quite well), the brain must aggregate only those cross-modal cues that are derived from the same event. Though it may use many stimulus features to make this judgment, the spatial and temporal concordance of cross-modal cues has proven to be a particularly effective criterion (see Stein and Stanford, 2008).

The resultant multisensory integration enhances the detection of an event or object, its identification (Giard and Peronnet, 1999; O'Hare, 1991; Angelaki et al., 2009; Stein et al., 1996), and the probability that the brain will initiate appropriate responses to it (Frens et al., 1998; Stein et al., 1989). It is not surprising then, that it also increases the speed with which those responses are programmed (Rowland et al., 2007a) and manifested (Frens et al., 1995; Goldring et al., 1996; Hughes et al., 1994; Bell et al., 2005). In short, it heightens the brain's sensitivity and reactions to environmental events. It is interesting to note that the physiological processes underlying these changes appear to be specific to cross-modal events; that is, multiple concordant signals derived from the same modality do not generate the changes detailed above, thereby distinguishing multisensory integration from unisensory integration. Given two sets of stimuli with approximate equivalence in efficacy, the cross-modal pair will produce much larger enhancements than the within-modal pair (Alvarado et al., 2007, 2008). This difference can also be observed at the behavioral level (Gingras et al., 2009), and is a likely consequence of the fact that in the former case, the signals represent conditionally independent estimates of an event variable, while in the latter case, the same factors that corrupt one of the signals will also significantly corrupt the other. These observations reinforce the utility behind the evolutionary strategy of developing and maintaining sensory systems that are distinct yet able to interact with one another.

Multisensory Integration and the SC

Multisensory integration is already effected at the initial level of information processing in the central nervous system, the single neuron. These multisensory neurons are found at nearly every level in the central nervous system (see Stein and Meredith, 1993), paralleling the distribution of areas devoted to processing information specific to individual sensory modalities.

As a consequence, higher animals have developed a curious duality: some areas of the brain are specialized for processing information on a sense-by-sense basis, and probably give rise to the peculiar subjective impressions that are so closely bound to one modality or another (e.g., the perceptions of color, pitch, tickle, or itch). Conversely, other areas are specialized for information processing regardless of the specific sense or senses from which that information is derived. These latter areas depend on a convergence of inputs from different senses onto a common set of (multisensory) neurons.

One of the best–known structures in which multisensory convergence occurs is a midbrain structure: the SC. In fact, researchers have leaned heavily on the responses of multisensory SC neurons to develop a model that is helpful

in understanding the general neural properties of multisensory integration, and this has proved to be an excellent strategy for a host of reasons. First, the SC is richly endowed with converging visual, auditory, and somatosensory inputs, and thus has many multisensory neurons that can be studied electrophysiologically. Second, the SC is also known to play an important role in producing motor actions that are guided by sensory stimuli. Specifically, it is involved in generating orienting behaviors to stimuli in contralateral space and, thus, for example, mediates rapid shifts of gaze (i.e., eye and head movements) to objects of interest. These factors make it possible to use the same structure to explore the principles governing multisensory integration at the neuronal and behavioral levels.

A multisensory SC neuron has multiple receptive fields, one for each sensory modality to which it is responsive. A receptive field defines the area of sensory space (e.g., visual space, auditory space, somatosensory space) where a given stimulus will be effective in activating the neuron. For multisensory neurons, their different receptive fields are in spatial register with one another. For example, a visual–auditory neuron with a visual receptive field in central space will be responsive to auditory cues in a roughly overlapping region of auditory space as shown in Figure 1. The spatial register among the modality-specific receptive fields of a multisensory neuron plays a critical role in its synthesis of cross-modal cues. Such register is characteristic of multisensory neurons regardless of where they are found in the nervous system, and is maintained even if, for example, one set of peripheral sensory organs moves. Any eye movement can shift visual space relative to auditory (head-axis) or somatosensory (body-axis) space because the retinal receptor cells have moved (Hartline et al., 1995; Jay and Sparks, 1984; Harrington and Peck, 1998). Rather than disrupt receptive field alignment in SC neurons, movement-induced misalignment of sensory reference frames sets into motion compensatory neural mechanisms that attempt to maintain receptive field register. Thus, a shift in eye position to the right produces a rightward shift in the auditory receptive field of an SC neuron (Harrington and Peck, 1998; Jay and Sparks, 1984). Similarly, there is even evidence that the somatosensory receptive fields of visual–somatosensory neurons show compensatory changes as a consequence of eye movements (Groh and Sparks, 1996). Although the mechanisms underlying these dynamic shifts in receptive fields are not well understood, using the retina as a referent for shifting nonvisual receptive fields in the SC reflects its principal role in generating gaze shifts to targets of any modality, including those that are multisensory. This is not the case everywhere multisensory neurons are found. In regions of premotor cortex, where visual–somatosensory neurons are found and whose activity generates limb rather than eye movements, movements of the limb produce compensatory changes in the location of visual receptive fields (Gentilucci et al., 1983; Graziano et al., 1994). Yet, once again, cross-modal receptive field register is a key element in the maintenance of a modality-independent coordinate frame to properly code movement.

Spatial

The enhanced multisensory response of a neuron depends on stimuli having access to its two (or more) receptive fields simultaneously or within a short window of time. Given the spatially overlapping nature of receptive fields in multisensory neurons, the activating stimuli should derive from the same location in space, such as when they originate from the same event. The consequent multisensory response typically is a train of discharges that contains more impulses than one evoked by either of the modality-specific stimuli. Indeed, if the modality-specific responses are themselves weak, the response to the combined stimulus often exceeds the arithmetic sum of the modality-specific responses (Figure 2).

If, however, the stimuli are derived from different locations (e.g., originate from different events), so that one stimulus falls outside its receptive field and is spatially discordant with the other stimulus, no such response enhancement is produced. In fact, under such circumstances there is a good probability that the opposite effect, response depression, will occur. In such cases, even vigorous visual responses can sometimes be

Figure 1 Stimulus traces (top), impulse rasters (middle), and peri-stimulus time histograms illustrating the responses of this neuron to visual (left), auditory (middle), and a spatiotemporally concordant visual–auditory stimulus pair. The multisensory response is clearly elevated over the largest unisensory component response (here, the visual), as illustrated in the summary bar graph on the right. Modified from Meredith, M.A., Nemitz, J.W., Stein, B.E., 1987. Determinants of multisensory integration in superior colliculus neurons: I. Temporal factors. Journal of Neuroscience 10, 3215–3229.

Figure 2 The presentation of two visual–auditory stimulus pairs, that differed only in their spatial coincidence, resulted in very different neural responses. (a) The individual receptive fields of a visual–auditory neuron are in good spatial register. The circles shown here are schematic diagrams of visual (left) and auditory (right) space. The intersection of the horizontal and vertical meridians depicts a point directly in front of the subject, and each concentric circle represents 10°. The left plot shows the location of a visual stimulus (icon) within its receptive field (indicated by shading), the middle plot shows the location of an auditory stimulus within its receptive field (the frontal half of auditory space is shown by the central sphere, and the caudal half is represented by the two hemispheres that have been split and folded forward), and the right plot shows the placement of visual and auditory stimuli within and outside the receptive fields. (b) Multisensory enhancement. Responses to a visual (V only), auditory (A only), and visual–auditory (VA) stimulus placed inside a multisensory neuron's receptive fields. Stimulus traces are illustrated on the top, impulse rasters in the middle, and peri-stimulus time histograms on the bottom. The bar graphs on the right summarize the response magnitudes for each stimulus condition. (c) Multisensory depression (conventions the same as in **Figure 2(b)**). In this example, the auditory stimulus was placed outside of the neuron's receptive field, evoking a depressed response when paired with the visual stimulus.

abolished (Figure 2). These changes at the single neuron level are reflected at the behavioral level as enhanced attentive and orientation responses to spatially coincident cross-modal stimuli, and depressed attentive and orientation responses to spatially disparate cross-modal stimuli (Stein et al., 1989).

These opposing effects of the same stimuli are believed to be due to a neuron receiving synergistic excitatory inputs when its two input channels are stimulated by spatially aligned stimuli (both stimuli fall within the excitatory receptive fields of that neuron), but, because some receptive fields have inhibitory regions at their borders, response depression can be explained by the antagonism between the inhibitory input from the stimulus outside the receptive field and the excitatory input produced by the stimulus within its receptive field (Kadunce et al., 1997).

Temporal

Integrated multisensory responses also depend on the relative timing of the stimuli. When the interval between two different sensory stimuli is too large, they are recognizable in the neuronal response as discrete events. In other words, no integration takes place. Nevertheless, for any given neuron this

temporal 'window' within which they can be integrated may be several hundred milliseconds and the window is generally predictable from the duration of its response to the first stimulus. So, for example, if a somatosensory stimulus elicits a response that lasts 200 ms, a multisensory interaction will occur if the activation produced by a stimulus of a second modality occurs during that period (Meredith et al., 1987; Wallace and Stein, 1997).

This is important because even though different senses may be activated by the same event, the speed with which the modality-specific components activate a multisensory neuron can differ substantially (auditory and somatosensory information reaches SC neurons in 10–25 ms, while visual information requires 40–120 ms). If precise coincidence were required, very few multisensory interactions would take place. Nevertheless, the temporal interaction window is finite and different neurons respond best to different stimulus asynchronies. Generally speaking, the magnitude of the interaction reflects the degree to which the modality-specific activation patterns overlap in time. Thus, the magnitude of the interaction diminishes rapidly as this period of temporal overlap declines (Figure 3). In some cases, temporal intervals that are transitional between those that produce enhanced responses and those that produce two independent responses give rise to response depression. In the case of visual–auditory neurons, the ability to respond differentially to stimuli with different input latencies suggests a tuning to events occurring at different distances from the animal.

Figure 3 The temporal window of integration for a multisensory interaction in one visual–auditory neuron. The magnitude of the multisensory interaction is plotted here as a function of the interval between the onset of the two stimuli (V = visual, A = auditory). Stimulus traces indicating the relative timing of each stimulus are located above peri-stimulus time histograms of the resulting response. The labels indicate the relative temporal offset between the stimuli; for example, A200V indicates the auditory stimulus onset preceded the visual by 200 ms, while V200A indicates the visual stimulus onset preceded the auditory by 200 ms. Summary statistics at the bottom illustrate % difference between the multisensory and best unisensory response for each temporal offset according to different metrics: response magnitude (% enhancement), mean discharge duration, and mean peak discharge frequency. All metrics show similar trends. In this neuron, simultaneous onset of the visual and auditory stimuli (V = A) produced the greatest multisensory enhancement. Different neurons showed their maximum multisensory response at different cross-modal intervals (generally within 50–100 ms of simultaneity) and had different temporal windows (generally 100–500 ms). Modified from Meredith, M.A., Nemitz, J.W., Stein, B.E., 1987. Determinants of multisensory integration in superior colliculus neurons: I. Temporal factors. Journal of Neuroscience 10, 3215–3229.

Whether there is some systematic organization of these neurons that may be helpful in localizing stimuli in three-dimensional space remains to be determined.

Inverse Effectiveness

The degree to which the response to a cross-modal stimulus exceeds that to each of its modality-specific component stimuli is generally inversely related to the effectiveness of those component stimuli. This makes intuitive sense if we consider the possible functional consequences of multisensory enhancement. By definition, very effective modality-specific stimuli evoke strong neural responses and are very likely to elicit a behavioral response. Thus, if the objective of multisensory enhancement is to increase the probability of detecting and/or responding to an event, there would be little gained from augmenting an already vigorous unisensory response. On the other hand, substantial benefit might be had by combining, and thereby enhancing the influences of weak modality-specific stimuli. The possibility that the system would then be overly susceptible to environmental and/or neural 'noise' is countered by the low probability of random spatial and temporal coincident activation of different sensory channels unless they are linked to the same external event. This logic has been the impetus for many organizations (most prominently, industry and the military) to use this biological system as a model for developing sensor-fusion devices for navigation, air traffic control, and even to search for objects embedded in 'noisy' environments such as the forest or sea floor.

The Essential Circuit for Multisensory Integration in SC Neurons

One might reasonably assume that any SC neuron receiving inputs from two different sensory modalities would have the ability to integrate these inputs. However, this is not the case. Multisensory SC neurons receive converging modality-specific inputs from many sources (see Stein et al., 1993) but cannot integrate their cross-modal inputs in the absence of inputs from a region of association cortex (see Alvarado et al., 2007; Jiang et al., 2001; Jiang and Stein, 2003; Wallace and Stein, 1994). As shown in Figure 4, when the SC is deprived of functional inputs from this region of the cortex (by reversibly deactivating it via cryogenic blockade), SC neurons retain the ability to respond to inputs from different sensory modalities, but lose their ability to integrate them and thereby enhance their

Figure 4 Inputs from association cortex are critical for multisensory integration in the SC. Shown here is a representative example of an SC neuron whose sensory responses were examined before, during, and after temporarily deactivating association cortex by cryogenic blockade (cooling). The top plots show the location of this neuron's visual and auditory receptive fields. (a) Under control conditions, this neuron exhibited a substantial multisensory response enhancement to the visual–auditory stimulus combination. (b) When a region of association cortex (the anterior ectosylvian sulcus, AES) was deactivated, this enhancement was abolished, even though the neuron retained its normal responses to the visual and auditory stimuli when presented individually. (c) Following rewarming of AES, the enhanced multisensory response was reinstated. Modified from Alvarado, J.C., Stanford, T.R., Vaughan, J.W., Stein, B.E., 2007. Cortex mediates multisensory but not unisensory integration in superior colliculus. Journal of Neuroscience 27 (47), 12775–12786.

responses. During cortical deactivation, they respond to combinations of cross-modal stimuli in much the same way as they respond to the most effective of the modality-specific component stimuli.

Presumably, these cortical deactivation-induced physiological changes in SC neurons would disrupt SC-mediated multisensory behaviors. A test of this was made by training animals to respond to visual cues in the presence or absence of auditory stimuli, and then testing them with or without this region of cortex deactivated (Figure 5). When the cortex was temporarily deactivated (with either a local anesthetic injection or cryogenic blockade), there was no change in the animal's responses to the visual cue, but the ability of the auditory cue to enhance (when spatially coincident with the visual) or degrade (when spatially disparate with the visual) these responses was severely disrupted (Jiang and Stein, 2003; Wilkinson et al., 1996). These behavioral observations, coupled with the electrophysiological results described above, demonstrate that the neural circuit in the SC essential for multisensory integration must include inputs from the cerebral cortex.

Development and Plasticity in Multisensory Integration

Although individual neurons in the neonatal brain are responsive to multiple sensory modalities, and in some species even multiple sensory modalities, no species thus far appears capable of multisensory integration at birth. This observation may be derived from the difficulty inherent in developing systems to coordinate activity across sensory systems with unique operational properties and constraints (e.g., time constants and sensitivities), or may reflect an adaptive strategy, whereby the organism postpones instantiating the expected spatial and

Figure 5 Multisensory orientation behaviors are affected by cortical deactivation as predicted from physiological studies. Three cats were trained in a perimetry device to orient to and approach an illuminated light-emitting diode (LED) for a food reward. During testing, the intensity of each LED was manipulated until each animal responded correctly to that LED on approximately 50% of the trials (white bars, V). The pairing of the auditory (speaker) with the visual stimulus at the same spatial location dramatically enhanced the probability of a correct response (visual + auditory). However, during deactivation of the left AES (shading on brain), these multisensory behavioral response enhancements were compromised in the contralateral hemifield (V + A/AES deactivated). Data are shown for stimulus locations from left to right: 45° left (−30°), 15° left (−15°), directly ahead (0°), 15° right (+15°), and 45° right (+45°). In agreement with the results of physiological studies (see Figure 4), responses to a modality-specific (visual) stimulus alone were unaffected by cortical deactivation (not shown). Modified from Jiang, W., Wallace, M.T., Jiang, H., Vaughan, J.W., Stein, B.E., 2001. Two cortical areas mediate multisensory integration in superior colliculus neurons. Journal of Neurophysiology, 85 (2), 506–522.

temporal relationships between common-sourced cross-modal signals until the unisensory systems themselves become better established and adapted to the environment in which the animal will live postnatally. Whatever the reason, the development of multisensory integration occurs gradually during the postnatal period in normal animals, reaching apparent maturity some time before adolescence. The development of multisensory integration appears to be highly dependent on the experience of the animal with cross-modal cues, such that in the absence of particular cross-modal experiences (e.g., by dark-rearing), neurons do not develop this capacity (Yu et al., 2010; Wallace et al., 2004), and given extensive experience with cross-modal cues having anomalous spatial or temporal relationships, integrate anomalously configured cues as if they belonged to the same event (Yu et al., 2009; Wallace and Stein, 2007).

However, plasticity in multisensory integration does not appear to be strictly limited to a particular developmental time window. Recent evidence suggests that extensive experience with cross-modal cue configurations in the adult can drive similar adaptive changes resulting in altered principles of multisensory integration, both in humans (e.g., Powers et al., 2009) and cats (Yu et al., 2009). In fact, animals deprived of early experience and developing without the capacity for multisensory integration can acquire these capabilities later in life with appropriate spatiotemporal cross-modal experience (Yu et al., 2010). These observations suggest a mechanism by which animals might continuously adjust the way in which they process cross-modal cues to adapt to environmental circumstances as they change.

Multisensory Integration among Different Species and Structures

Although many of the specifics that were presented earlier were drawn from experiments in cats, most of the sensory features that characterize the SC of this animal are also found in every other laboratory species that has been examined thus far. Particularly important in the current context is the spatial register among the different receptive fields of multisensory neurons. This has been found in rodents, carnivores, and primates. The widespread nature of this scheme for coupling inputs from different sensory modalities, and its presence in neurons of the nonmammalian homologue of the SC, the optic tectum (see Stein and Meredith, 1993), suggest that it was preserved during the transition from nonmammalian to mammalian forms and is adaptable to a wide variety of ecological circumstances.

The utility of multisensory integration is not restricted to neurons involved in SC-mediated behaviors, as it is also characteristic of multisensory neurons in many neocortical areas (e.g., Bruce et al., 1981; Duhamel et al., 1991; Fogassi et al., 1996; Graziano et al., 1997; Gu et al., 2008; Ramachandran et al., 1993; Rizzolatti et al., 1981a, 1981b; Stein et al., 1993; Wallace et al., 1992), where such neurons are likely to be involved in functional roles very different from those involving the SC. Although many of the basic principles of multisensory integration (e.g., spatial and temporal congruence) may transcend structure, function, and species, the computational rules that govern its expression are likely to depend on the specific function to be carried out (Stein and Stanford, 2008). For example, multisensory enhancement, a neural correlate of stimulus salience, may not be prevalent, or even advantageous, when multiple modalities of information are combined for the purpose of perceptual evaluation, as for example, when visual and vestibular cues are combined for the purpose of estimating one's movement with respect to the environment (see Angelaki et al., 2009; Stanford, 2012). Future studies will be necessary to reveal the full scope of multisensory representation within the computations that neurons perform.

Computational Approaches to Multisensory Integration

There is substantial interest in developing theoretical frameworks to facilitate our understanding of the similarities and differences that are noted in the operation of multisensory integration in different circuits and species. Computational modeling provides a set of methods on which these links can be founded, in two ways: (a) offering rigorous quantitative formulations of empirical findings, and (b) translating behavioral and physiological observations into a common mathematical language. Recent models of multisensory integration operating at the physiological (Patton and Anastasio, 2003; Knill and Pouget, 2004; Rowland et al., 2007b; Cuppini et al., 2010; Ohshiro et al., 2011) and behavioral (Ernst and Banks, 2002; Colonius and Deiderich, 2008) levels provide insight into how basic computational mechanisms can be used to explain large collections of empirical results. Simultaneously, efforts illustrate how direct links between the neurophysiology and behavioral expressions of multisensory integration can be established through a common mathematical frame of reference (Angelaki et al., 2009). These efforts indicate the inherent power of the computational approach, which will be critical to determining if there exists a common set of principles by which information is pooled across the senses, or whether the brain has developed mechanisms specific to circuits intimately tied to their functional role for this purpose. Ultimately, the goal is to determine whether or not there is some fundamental aspect of the combination of information across the senses that supports a single global theory, or whether there are many.

Multisited Field Studies

Mark-Anthony Falzon, Clare Hall, Cambridge, UK; and University of Malta, Msida, Malta

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In the last couple of decades, multisited field studies (usually in their 'multisited ethnography' incarnation) have emerged as a methodological choice that favors a spatially dispersed field – through the use of actual multiple sites and/or the juxtaposition of data – through which social scientists 'follow' people, goods, information, and such. The knowledge that is produced is said to better reflect contemporary thought on space, place, scale, and boundaries, and therefore social formations that are caught up in contexts of transnationalism and globalization. The idea has spawned a considerable methodological–theoretical literature as well as a number of empirical case studies. It has also come under significant criticism, mainly from arguments of holism, lack of depth, and abdication of ethnographic responsibility. These critiques have led to a self-examining 'second-generation' thought and method and multisited studies show no signs of being forgotten.

'Multisited field studies' can mean many things. In the social sciences, the term usually refers to a type of grounded research based on ethnographic principles and techniques. In this standard incarnation, it is known as 'multisited ethnography,' which means that while the two terms are broadly interchangeable, most of the productive theoretical and empirical contributions hinge on multisitedness as applied to ethnography specifically.

Ethnography is an eclectic methodological choice that privileges an engaged, contextually rich, and nuanced type of qualitative social research, in which fine-grained daily interactions constitute the lifeblood of the data produced. With respect to method, it entails the situational combination of field techniques (note taking, audio/visual recording, interviews, examination of indigenous literature, observation, and such) rooted in the ideal of participant observation (to live, to some extent, as the 'natives' themselves do), itself based on relations of trust and a belief that data are produced in and of 'thick' interaction between researcher/s and researched.

Conventionally, ethnography has involved the idea – if not necessarily the practice – of a relatively long-term (typically several months upward) stay in a field site of choice. The site was understood to be the container of a particular set of social relations, which could be studied and possibly compared with the contents of other containers elsewhere. To some extent, the contents might also be generalized into area, regional, or, most optimistically, universal knowledge.

Multisited ethnography purports to break with this convention. The standard reformative thesis was nailed by George E. Marcus to the door of the *Annual Review of Anthropology* (1995). Telegraphically, Marcus argued that multisited ethnography defines as its objective the study of social phenomena that cannot be accounted for by focusing on a single site. Previously, the 'world system' was seen as a framework within which the local was contextualized or compared; it now becomes integral to and embedded in multisited objects of study. The essence of multisited research is to *follow* (a crucial and consequential word in this case) people, connections, associations, and relationships across space, because they are substantially continuous but spatially noncontiguous. Research proceeds by a series of juxtapositions in which the global is collapsed into and made an integral part of parallel, related local situations, rather than something monolithic or external to them. In terms of method, multisited ethnography involves a spatially dispersed field through which the ethnographer moves – actually, via sojourns in two or more places, or conceptually, by means of techniques of juxtaposition of data.

Since 1995, Marcus – sometimes in collaboration with other scholars – has pursued an ongoing project of 'refunctioning ethnography' (Holmes and Marcus, 2004, 2005). The significant number of sophisticated articulations of what multisited ethnography might actually mean, in theory and practice (see, for instance, Hannerz, 2003; Gustavson and Cytrynbaum, 2003), can also be read as developments on the theme. The consensus is that much new ground has been covered since the 'first-generation' multisited ethnography. This openness to self-renewal and self-criticism, spearheaded in many ways by Marcus himself, is what has kept the idea so full of life and potential.

Predictably, reactions to Marcus's program have been mixed. On the one hand, there are those for whom the idea is so much old wine in new bottles. On the other, it has fired the spatial imagination – and enlarged the carbon footprint – of a generation of social scientists, as the converts used it to study things as diverse as global environmentalism (Gatt, 2011), climate change (Krauss, 2009), human immunodeficiency virus/acquired immunodeficiency syndrome (Whyte et al., 2011), and even a type of gourmet mushroom (Choy et al., 2009). Methodologically too, multisited ethnography has been the subject of a great many scholarly contributions; these include at least two edited collections (Falzon, 2009; Coleman and von Hellermann, 2011).

Empirically, the most productive venue has probably been that of mobility studies ('follow the people,' as Marcus would put it). Given the extent to which scholars in the field have largely eschewed 'methodological nationalism' in favor of transnational understandings, this is hardly surprising. As Amelina and Faist put it, the transnational approach "rejects the nation-state as the sole starting point of empirical analysis … [and] … calls for a denaturalization of categories such as 'nation' and 'space'" (2012: p. 2). What that means in practice is that migration scholars increasingly find it uncomfortable to root their research – physically and/or conceptually – in a single site. Amelina and Faist go on to describe how

multisited ethnography has also inspired the 'mobile methods' ethnographic approach, an itinerant strategy that recommends collecting data by 'observing people's mobility,' 'walking with,' 'stalking,' or 'lurking' around others. This supposedly produces an intimate knowledge of, and enters into a dialectical relationship with, geographical and/or virtual mobility. According to this position, transnational scholars would need to go beyond *sui generis* models of state responses to mobility and look at the practices of (potential) migrants, which may result in mobility, immobility, or a combination of both.

Somewhat cheerfully, the idea also seems to have spilled over into disciplines other than anthropology and sociology. 'Multisited archaeology,' for example, is "adapted from multi-sited ethnography to serve archaeologists' interests in comparing locales, multi-scalar connections, and local-global relations" (Ryzewski, 2012: p. 241).

It must be said that déjà vu is not the only finger that has been pointed at multisited ethnography. In the last few years, especially, one has also seen a number of sustained and serious critiques of Marcus's original formulation and its elaborations. Hage (2005), for instance, who mischievously suggests that multisited imaginings may well be a symptom of delusions of innovativeness if not grandeur, argues that with respect to studying, say, migration, the concept of a single geographically discontinuous site is much more useful than that of multisitedness. He also suggests that multisited research may imply a tacit holism, and proposes that a "certain reflexivity concerning the social relations that one is opting not to cover in depth" (Hage, 2005: p. 466) makes for a better definition of one's partiality. His conclusion is startling: "I simply do not think that there can be such a thing as a multi-sited ethnography" (Hage, 2005: p. 465). For Hage, multisited ethnography is a buzzword, since "its signification and ramifications are [not] explored by many of its users … [who] use it mechanically" (Hage, 2005: p. 464).

A second significant recent critique of the multisited imaginary is that by Matei Candea (2007). Like Hage, Candea targets in particular what he sees as a born-again holism implicit (and sometimes explicit) in Marcus's and subsequent formulations. He argues that ethnography is really about setting up 'arbitrary locations' – which in any case it invariably does, in the sense that a landmark work like Garsten's *Apple World* (1994) is actually Apple 'places,' since her ethnography of the multinational company was based on fieldwork in a *limited* number of locations *chosen by herself*. Candea grants that the multisited program has probably served to broaden the range of topics considered suitable for ethnographic study; however, he posits that Marcus's device of 'following,' for instance, could be applied equally well in a local, arbitrary setting – which is what ethnographers have pretty much always done. What the more naïve advocates of multisitedness see as 'incompleteness,' Candea sees as a self-critical methodological decision ('making the cut'), which one 'reflects upon and takes responsibility for' (Candea, 2007: p. 174). Ethnographers need to be more cautious of the seductions of 'limitless narrative possibilities' – which are deceptive in any case – opting instead for 'sensibilities based on self-imposed restrictions' (Candea, 2007: p. 168). Perhaps most importantly, Candea reminds us that siting is, as Coleman and von Hellermann put it, "an epistemological, methodological, and presumably political practice" (2011: p. 7).

A third line of critical thought takes to task Marcus's prescription for field-workers to 'follow.' The problem is that 'following' implies cartographies and trajectories that precede, and would exist quite happily independently of, the fieldwork project (see, for instance, Fairhead, 2011). In this sense, 'following' comes dangerously close to being a passive act and the field to being essentialized and detached from the field-worker – a far cry from say Dilley's (1999) convincing discussion on ethnographic context as a performative act. Recent contributions have tended to get around this by replacing 'following' with terms that are active and agentive. Coleman and von Hellermann (2011), for example, emphasize that there has been a conceptual shift from 'following' to 'collaborating': "We might be tempted to use the term 'fieldmaker' here, but we need to bear in mind that fields are always made, are never 'natural […]'" (p. 3). In fairness, the shift is evident in Marcus's own methodological thought and practice: A work like *Ocasião: The Marquis and the Anthropologist, a Collaboration* (Marcus and Mascarenhas, 2005) is true to its subtitle and indeed breaks new ground in that direction. Besides, once the substitution is made in favor of collaboration, multisited ethnography can quite easily deal with critiques from arbitrary decision making.

In view of these and other critiques, it may be worth remembering that there is a sense in which every fieldwork project is an experiment in siting the object. Rather like the Weberian ideal type (see, for instance, Freund, 1968), an analytical device by means of which the social scientist sets up the boundaries of a definition and proceeds to work within it (thus opening up infinite possibilities of ideal-typic definition and therefore analytical trajectories), any exercise in siting is always one of an infinity of possibilities. Clearly, the process should be based on more than whim; rather, siting proceeds within a triangular space set up by one's preunderstanding (itself a product of the current scholarly literature among other things), the developing researcher-researched collaborative exchange, and – last but not least – scholarly creative choices that are invariably circumscribed by the availability of resources. There are many reasons why this model of siting is useful. First, and pace Hage, it takes multisitedness to be one of a number of possibilities, rather than a messianic calling or a first among equals; this is both realistic and prudent. Second, it allows the notions of arbitrariness, choice, and creative scholarly enterprise happily to coexist with multisitedness in ways that transcend wooden models of 'following.' Third, it accommodates the recent thought on ethnography (including its siting) as a form of active and ongoing collaboration in the field.

The Methodological and Intellectual Background

In order to try to take stock of multisited ethnography, it makes sense to outline some of the reasons why the idea emerged when it did, and why it is thought to be so apt (according to some, necessary) an approach to contemporary research. The question may be phrased as, Why did the localizing strategies

of ethnography come into question, and why in the late twentieth century? Briefly, the author thinks that there are two main reasons.

The first has to do with the notion, and its ethnographic consequences, that space is socially produced. Lefebvre (1991 [1974]) was the first to flesh it out in a sustained way, the story goes, although Foucault was foresighted enough to sense, years earlier, that the 'spatial turn' was round the corner (see Soja, 1989). Definitely by the 1990s, space was all over the social sciences. As summed up by Massey (2005: p. 9), contemporary sensitivity to issues of space rests on three propositions:

> *First*, that we recognise space as the product of interrelations; as constituted through interactions, from the immensity of the global to the intimately tiny … *Second*, that we understand space as the sphere of the possibility of the existence of multiplicity in the sense of contemporaneous plurality; as the sphere in which distinct trajectories coexist; as the sphere therefore of coexisting heterogeneity … *Third*, that we recognise space as always under construction.

There is of course, in ethnography as well as in other social scientific circles, a long tradition of looking at the relation between people and spaces – at the making of places, in other words. What is more recent is the reflection on the methodological corollary of this relation. By 1986, Salzman (1986: p. 528) was asking "Is traditional fieldwork outmoded?", and suggesting among other things research-team models of ethnographic practice. (The suggestion has been taken up by scholars who have explored, often through their own empirical work, some of the ways in which multisited collaborative ethnography involving teams of people might work – see, for instance, Choy et al., 2009; FitzGerald, 2012.) Ten years later, Fog Olwig and Hastrup suggested that "the methodological implications of this insight [that space is socially produced] are still being worked out" (1996a,b: p. 1, the author's parenthesis). The upshot is that social science has had to come to terms with the idea that, logically, if space is produced, there is no reason why the spaces of field studies should be exempt. Marcus's plea may be seen as an attempt to prescribe a methodological antidote to these anxieties.

Aside, the 'spatial turn' has affected fields beyond the social sciences. In literary criticism, for example, recent years have seen a spate of works dealing with the spatialization of the text. Davidson (2007), for example, links free verse, and the way that the shape on the page is produced by the poem, to the Lefebvrian concept that space is not prior to but produced by human activity; Huang (2006) looks at 'spatial negotiation' in Asian-American fiction; and Michelucci (2002) draws on the works of D.H. Lawrence to discuss place as a culturally constructed category that exists in relation to space as a physical and philosophical one.

The second set of forces that inspired Marcus, and that lend allure to multisited ethnography, may analytically be separated into two types: first, the debatable (and debated) idea that contemporary societies are invariably, inevitably, and self-evidently located within larger wholes (see Cook et al., 2009); second, the seemingly obvious corollary that within these wholes, people, information, goods, and ideas are in a constant state of displacement.

There is a sense in which a cautious analytical holism seems to be at the heart of the ethnographic approach. At the same time as ethnography is about the particular, it is also thought to give, as Gay y Blasco and Wardle (2007: p. 43) put it, "further contextual meaning to particular lives by demonstrating their integration within more inclusive social forms." Applying this to space/place, the question of what to do with the local has a long pedigree in ethnographic methodology. For example, during the latter half of the twentieth century, anthropologists – in particular those studying seemingly bounded peasant villages, or 'immigrant communities' – became increasingly uncomfortable with the conventional idea that the local was an adequate form of ethnographic space (Falzon, 2005). Even so, as recently as 2007, Russell (who went on to do multisited fieldwork with the Yakkha people in Tamaphok, Nepal, and various migrant destinations in India and elsewhere) could complain that migrants are people one says 'hello' or 'goodbye' to in their destinations and places of origin, respectively, "but rarely with knowledge … of the travels and travails in between" (2007: p. 362).

The grandest themes of late-twentieth century and contemporary social science seem to revolve around a problematic relation to the local and the search for some larger scale of analysis, and the study of connections between places. As Mintz (1998: p. 117) puts it, "(t)he new anthropology is many things, among them the study of human groups *in motion*. That motion is thought to be more than international; it is *trans*national." World systems theory, transnationalism, migration studies that go beyond classical push–pull and/or integration concerns, diasporas, cosmopolitanism, and so forth – all posit frameworks and scales that invite supralocal understanding and therefore methodology. The most prominent interpretive framework is of course that of globalization, which as a paradigm patterns much of the contemporary thought about people and places. A host of social formations are nowadays seen as being formed and reformed in and of 'global assemblages,' in Ong and Collier's words (2005).

One should add that recent formulations of globalization have moved well away from both the 'global village' model and its less banal if more insidious cousin, namely, the idea that global interconnectedness coexists with local variability. As Massey (2005: p. 88) puts it, "'spatialising globalisation' means recognising crucial characteristics of the spatial: its multiplicity, its openness, the fact that it is not reducible to a 'surface', its integral relation with temporality." The shift is relevant because it raises the cardinal point that while multisited ethnography may be many things, what it certainly is not (or should not be) is an approach that devalues locality and place. On the contrary, multisitedness properly done has the potential to produce a knowledge that highlights the specifics of place and local experience and the hierarchies that these exist within, and that in turn provides the basis for an informed critique of place and location. In other words, multisitedness assumes that place still matters. The alternative would be an aspatial multisitedness, a notion that mocks itself so effectively that hardly any explanation is required.

The point is that the paradigms of globalization and its cousin, transnationalism, no doubt posed the major twentieth-century challenge to ethnographic methods of inquiry and units of analysis by destabilizing the embeddedness of social

relations in particular communities and places (Gille and Ó Riain, 2002). As such, they were also behind the multisited model; indeed, for Hannerz (1998), for example, 'transnational research' is broadly interchangeable with Marcus's own terminology. It is commonly thought that a refusal by ethnography to engage with a type of spatialization associated in the popular (and sometime the scholarly) imagination with modernity would (unacceptably) limit practitioners to an ever-tighter circle of apparently bounded locales.

Clearly, the earlier point about space and the present one on the space of modernity are directly linked. If, as summed up by Marshall Berman's (1983) application of a famous sentence, modernity is about 'All that is Solid Melts into Air,' that includes ethnographic space and field siting. Again, Marcus's and subsequent contributions have provided a useful point of departure. Cook et al. (2009), for example, have suggested that one way of reformulating multisited ethnography is by conceptualizing the field in such a way as to detach it from the concepts of space and place, thus opening up the possibilities of an 'unsited' field within which comparison across theoretically relevant spatial boundaries can take place. They emphasize that unsited fieldwork is a development on, rather than a negation of, multisited ethnography.

Anxieties and Comforts

Much of the discussion on multisited ethnography revolves around the idea that it may well be an oxymoron. That is, there exists a preoccupation that while there is much to be said for researching spatially dispersed objects, a program that proposes to be more routes than roots (see Clifford, 1997) could well end up robbing ethnography of its central tenets as presented earlier, and therefore of its value as the jewel in the crown of qualitative research. This preoccupation is not necessarily born of a purist conservatism (although that element is at times present), but rather of the belief that the ethnographic paradigm – traced to Malinowski by anthropology and to early-twentieth century urban studies by sociologists – has produced some of the richest social scientific insights, and is as such worth preserving. Hage epitomizes this belief: "[A]fter spending so many years examining all kinds of work in the areas of migration and diasporic studies, I have consistently found it to be the case that of all the disciplines deployed in studying globalization, migration and mobility, none are better equipped … than an ethnographic analysis" (2005: p. 474). The two main sources of anxiety (both of which have been referred to earlier) concern depth and ethnographic responsibility.

'Depth' – or, as Geertz (1973) famously put it, 'thick description' – is unquestionably one of ethnography's richest offerings. Its lack is also thought to be a key flaw of the multisited project, which seems to lead field-workers into spreading themselves too thinly. Briefly put, given that this type of research implies moving around and 'following' horizontally, there is little time for staying put and achieving depth by 'following' vertically. As Burawoy put it, "[b]ouncing from site to site, anthropologists easily substitute anecdotes and vignettes for serious fieldwork […]" (2003: p. 673).

In order to address this issue, one must question the process of production of depth/thickness in conventional ethnography; only then can one decide whether or not multisited ethnography measures up. Participant observation is the obvious answer, but what about it? The methodological stance of 'getting off the verandah' or 'hanging out' at street corners is only part, albeit a necessary one, of the story. Crucially, the factor that enables ethnographers to achieve depth and to make informed decisions about the partiality of their work is time. Participant observation has its own time order, which typically runs to several months. Initiates believe that the growth of ethnographic consciousness reveals itself to the field-worker as water boils, that is not only gradually but also through a defining moment, at which one suddenly realizes that one 'understands.' The moment of inspiration itself may be abrupt but it is actually the product of that gradual process. Prospective field-workers are told that, provided they stick it out long enough, their moment will come. In ethnography, therefore, time transforms and makes. We might here take a leaf out of Bourdieu's writing on the implicit (and therefore unquestioned, by researchers and researched alike) periodicity of gift exchange, to the effect that it is not just the nature of the gift that gives it meaning but also its *timing* – "to abolish the interval is to abolish strategy" (1977: p. 6). The contention is that by abolishing the interval, multisited ethnography abolishes depth.

There are at least four counterarguments and/or -proposals. The first argues that multisited fieldwork does indeed present these logistical and methodological challenges, and that the solution is to choose one's sites as carefully as possible in such a way that the periods spent in each site add up to an acceptable interval. In addition, careful field strategies are needed to maximize the dividends in each site, given the limited time. In FitzGerald's words, "[t]he danger of stretching time and resources too thin in multi-sited fieldwork is why it is even more dependent on a clear theoretical orientation and strategic site selection than work in a single site. Fumbling through one field site to ground theory is bad enough; in multiple sites it is disastrous" (2012: p. 3). One supposes that the criteria for site selection will be case specific and will vary according to one's resources, research questions, and ongoing collaboration in the field.

The second is to substitute long-term with very long-term fieldwork, thus enabling one to 'take in' more sites. A reasonable proposition, which, however, makes rather special demands on the field-worker. Leonard (2009), for instance, has shown how she adopted a long-term cumulative strategy by making a particular project her life's work, so to say.

The third argument, which is popularly – and probably unfairly – associated with first-generation formulations, is that the multiplicity of multisitedness makes up for its inadequacies in any single site. That is, as ethnographers move around, it becomes a matter of adding short durations to make a long one. The argument is clearly flawed in that two or more shallownesses do not make a depth; intervals simply do not add up, or at least not unproblematically.

The fourth solution is much more compelling. There is a sense – to some extent implicit in notions of 'time–space compression' and such – in which space and time are methodologically interchangeable. In other words, it is not just time that transforms and makes, but also space. This porosity has always been part of the ethnographic paradigm, not least

since conventional ethnography posits a long stay *in one place* (hence the relevance of space). And historically within anthropology, fieldwork 'away from home' (therefore, spatial displacement) was also seen as a prime route to what textbooks call 'defocusing,' an ethnographic state of mind, which in turn enables the production of data.

Clifford's writings on route-based research and the conventionally backgrounded spatial shift of 'getting there,' are well known (1997). In addition, one might argue that just as classical foundation myths have the *oikists* (founders) mark out a new city's boundaries or sacred temenos by circumambulation, ethnographers have classically set up spatial routines that enabled them to know a people by knowing a place. The ethnographer turns out to be a serial circumambulist, daily retracing their steps and in so doing producing the site and knowledge about it. Spatial routine becomes a route to ethnographic knowledge.

The time/space swap is important because it enables one to suggest that it is precisely the paradigm of participant observation (as the main portal to the native's point of view) that constitutes the strongest case for multisited ethnography. If our object is mobile and/or spatially dispersed, multisited field studies become themselves a form of participant observation by virtue of having those characteristics. As Clifford (1992) puts it, they can be seen as 'fieldwork as travel practice.' And, if conventional depth is hard to come by in unsettled circumstances, that is probably as things should be, in the sense that it represents the way people *themselves* experience the world. Russell, who cites Clifford's work extensively, is himself worth quoting more fully: "[I have] done this [fieldwork as a form of travel practice] through the example of a thirty-six hour sojourn with a historically migrant Yakkha family met fortuitously while I was 'on the road' … Such experiences help to expand, and challenge, the conventional geographical and socio-cultural boundaries of groups such as the Yakkha" (2007: p. 378, the author's parentheses).

This raises an empirical question: If it is indeed the case that multisitedness may itself be seen as a form of participant observation, what sort of tangible on-the-ground things might it help us observe, participate in? The examples that come to mind include the re-/localization dynamics and strategies of mobile groups, the production of located presence in cyberspace (see, for instance, Gatt, 2011), local experiences of geographically broad religious transformations, and the ways in which individuals and groups commute between the various scales (see Herod, 2011; the discussion in Coleman and von Hellermann, 2011) that frame social experience.

In addition, the point has been raised by FitzGerald (2012) that being multisited and having multisited knowledge are excellent ways of gaining access to one's people and eventually building rapport. It is surely relevant that FitzGerald worked with Mexican migrants (again, 'follow the people') – with a group, that is, for whom mobility and knowledge of places are particularly desirable attributes. Likewise, in his fieldwork with Sindhis, Falzon (2005) holds that being mobile and flaunting it turned out to be very effective as a means of earning his informants' respect and trust. Again, however, Sindhis are a group that particularly prizes a kind of multisited spatial fluency.

The second source of anxiety with respect to multisited field studies derives from considerations of ethnographic responsibility. Consider the following piece of postfield recollection:

> Now, if I wanted to carry out research on Gibraltarian Sindhis, where should I do that? Would I have to go to Madrid, where Ramesh Karnani was on the brink of opening a subsidiary of his father's shop? What about cousin Gope, who studied law in London? What about Anusha, whom I met in 1996 and considered a typical 'Gib-girl' of Indian origin, and in 1997 married a Sindhi from Manila, where she lives today? And how to meet Aunt Geetu from Bombay, who has never left India in her 64 years but who is in regular contact with her relatives in Gibraltar, who keeps contact with her family guru in Bombay and who probably knows more about her family in Gibraltar than anyone else living in the colony? (Haller, 2005: p. 155)

One charge that is sometimes leveled at the multisited program is that, in advocating 'following,' it appears to assume a preexisting field – a 'given' space or set of trajectories produced by the people, goods, information, and so on that are being followed. Clearly, that would go against the basic principle that space is socially produced, in this case by both researcher and researched. In other words, the very logic of contemporary understandings of space (as discussed earlier) requires that ethnographers take responsibility for the production of their field sites.

Marcus's line of thought since the original 1995 paper, as well as a number of recent scholarly contributions (see, for example, the discussion in Coleman and von Hellerman, 2011), address this problem by suggesting that the process of siting is essentially a collaborative one (as discussed earlier). It is thus that ethnography retains its ethnographic responsibility, and that practitioners are reminded that they have an important part to play in the dynamics of carving out a site – theirs is a shared responsibility, so to speak. Viewed this way, multisited ethnography is a form of, to use a term from Marcus (1998), 'complicity.' As law teaches us, complicity is still a very real, if partial, responsibility.

Perhaps more importantly, the notion of partial ethnographic responsibility opens up the whole field of looking at ways in which it is produced; surely, this must be one of the more useful corollaries of Marcus's program. As Gille and Ó Riain (2002: p. 289) put it, "[t]he extension of the ethnographic site in space and time sharpens one's sensibilities to the political consequences of defining a site or sites." The methodology of multisited field studies has come a long way from straightforward notions of 'following.'

In conclusion, one might ask whether or not Marcus's call has produced anything of lasting value. It would appear that multisitedness is not by nature a buzzword, although it may be and indeed has on occasion been bandied about as such. Especially when one takes into account the ongoing critiques (including Marcus's own) and increasing theoretical sophistication, it has made at least three contributions to the field:

- first, a heightened methodological and theoretical sensitivity to space, place, scale, and boundaries, and to the ways in which they are manufactured and experienced both by ethnographers and by the people they work with;
- second, a shift toward collaborative field-making and research and therefore toward an ethnographic knowledge

that is better aware of, and intellectually equipped to experiment with, the processes of its coproduction;

- third, an ongoing discussion – and actual empirical results – of some of the practical ways in which ethnographers might go about producing this spatialized and collaborative knowledge.

The place may look familiar but multisited ethnography has thus far turned out to be anything but a methodological cul-de-sac.

Multistate Transition Models in Demography

This article is a revision of the previous edition article by D. Courgeau, volume 15, pp. 10210–10214, © 2001, Elsevier Ltd.

Abstract

Multistate transition models provide an analytical framework for situations in which there exists a certain number of 'states' of interest that individuals can occupy, and between which individuals can move. Multistate models allow one to describe these situations by examining patterns of transitions across states and estimating state-specific life expectancies. This article emphasizes the basic properties of multistate transition models, as well as practical strategies for estimating them.

Introduction

In demography, multistate transition models refer to situations in which there exists a certain number of 'states' of interest that individuals can occupy, and between which individuals can move (Rogers, 1975; Land et al., 1982; Schoen, 1988a,b). Examples of 'states' include the following:

- 'Residing in urban areas' versus 'residing in rural areas.' In this example, transitions between states refer to migrations from urban to rural areas and vice versa.
- 'Having no disability' versus 'being disabled.' In this example, transitions between states refer to the incidence of disability (transitions from having no disability to being disabled) and to recovery from disability (transitions from being disabled to having no disability).
- 'Being never married'; 'being married'; 'being divorced'; 'being widowed.' In this example, transitions between states refer to various changes of marital status, including the incidence of first marriage (transitions from 'never married' to 'married'), the incidence of divorce (transitions from 'married' to 'divorced'), etc.

In all the above examples, there necessarily exists an additional state, namely, the state of 'being dead.' Transitions to that state represent mortality. A multistate transition model contains a minimum of two 'living' states, in which individuals can spend a certain amount of time, as well as the state of being dead.

An important feature of multistate transition models is that they allow the study of situations in which individuals can move back and forth between the different 'living' states of interest. This contrasts with single state models, like the classic life table, in which only one transition is possible with no possible return to the state of origin, that is, from 'being alive' to 'being dead.'

Multistate transition models in demography allow one to quantify patterns of transitions between states and study how they vary over age and time. These models also allow one to calculate a number of interesting quantities that result from given transition patterns. For example, if we take the marriage formation model described above, the multistate framework allows one to calculate the following quantities of interest:

- How many years can a newborn expect to live in the 'married' state?
- How many additional years can a person in the 'divorced' state at age 50 expect to live in the 'married' state?
- What is the probability that a marriage will end in a divorce?
- What is the probability of remarriage from divorce or widowhood?
- What is the probability that a newborn will die in the married state?

This article is organized as follows. First, I discuss the simple case of transition models without age. The next section introduces age with a discussion of multistate life tables. The last section discusses multistate population models, i.e., models in which patterns of entry into the multistate system are integrated (for example, via births), generating populations with interesting properties.

Multistate Transition Models without Age

In their simplest form, multistate transition models do not include age: the population of interest is broken down by state but not by age. For example, let us consider a population broken down into two states: urban population versus rural population. A simple multistate model allows one to examine patterns of migration between urban and rural populations and how these populations grow or decline over time as a result of these transitions. Assuming that the overall population is closed to international migration, the following forces are affecting the size of the urban and rural populations:

- For the urban population: the crude rate of natural increase (defined as the difference between the crude birth rate and the crude death rate for the urban population) and the crude rate of out-migration (from urban to rural areas).
- For the rural population: the crude rate of natural increase (here defined for the rural population) and the crude rate of out-migration (here from rural to urban areas).

An interesting feature of this model is the interdependence between the two states: the size of the urban population affects the size of the rural population through out-migration from urban to rural areas, and the size of the rural population affects the size of the urban population through out-migration from rural to urban areas. This is an important feature shared by all multistate transition models.

Another important feature of this model is that if rates of natural increase and out-migration remain constant over time for both urban and rural populations, eventually urban and rural populations will be growing at the same rate, and the proportionate distribution of the population by urban/rural residence will become constant. This eventual state of equilibrium is independent of the initial distribution of the population by urban/rural residence. This is illustrated in Figure 1, which shows trajectories toward equilibrium in populations with proportion urban ranging from 10% to 90% at baseline. Assuming a crude rate of natural increase of 20 per 1000 in urban areas and of 30 per 1000 in rural areas, and a crude rate of out-migration of 10 per 1000 in urban areas and of 30 per 1000 in rural areas, populations will all reach an equilibrium proportion urban of 69.7%, regardless of the initial proportion urban. This equilibrium proportion is entirely the product of the assumed constant rates of natural increase and out-migration.

Multistate (Increment–Decrement) Life Tables

Multistate life tables are a different but related kind of multistate transition model. Instead of following a population over time, like in the above example, a multistate life table follows a cohort through different ages. Members of a cohort are born in a given state, and as they age they may move through different states, until they eventually die. A multistate life table describes and quantifies this process.

Multistate life tables are also called increment–decrement life tables because the number of individuals in one state can increase or decrease with age, depending on the balance of flows in-and-out of that state. This contrast with the classic life table model where the number of people in the state of 'being alive' can only decrease with age.

Multistate Life Tables for a Cohort

Multistate life tables are usually calculated for periods (using synthetic cohorts), but are best understood by looking at a real cohort and tracking cohort survivors over time as they move between different states. Therefore, we first discuss features of a multistate life table by looking at the case of a cohort.

For example, let us examine the simple case of a multistate life table model representing marriage formation, in which there are three states: (1) unmarried; (2) married; and (3) dead. Figure 2 represents the three states and the arrows represent possible transitions between the states.

It can be assumed that all individuals are born in the 'unmarried' state. As individuals age, they may transition between states: they may become married and then return to the 'unmarried' state through divorce or widowhood; they may move back to the state of being married through remarriage. Eventually, due to mortality, all individuals transition to the 'dead' state, either from the 'unmarried' state or from the 'married' state, depending on their marital status at the time of death.

A multistate life table summarizes the history of the cohort with the following columns:

- x = exact age;
- l_x^i = number of individuals in the cohort who are in state i at age x.

For example, in the marriage model described above, we have

l_x^U = number of individuals in the cohort who are *unmarried* at age x;
l_x^M = number of individuals in the cohort who are *married* at age x.

Figure 1 Proportion of the population living in urban areas for populations in which rates of natural increase and rates of out-migration are set to specific values and constant over time. In this example, all populations converge to a proportion urban of 69.7%.

Figure 2 Possible transitions among states in a simple marriage formation multistate model.

Note that l_x^U or l_x^M may increase or decrease with age (which is why, as said earlier, multistate life tables are also called increment–decrement life tables). Note also that $l_x^U + l_x^M = l_x$, the number of cohort survivors at age x. l_0 is the initial size of the cohort (at birth). In this example, all individuals are unmarried at birth, so $l_0^M = 0$ and $l_0^U = l_0$. In other examples, individuals may be distributed across more than one state at birth. For example, in an urban/rural residence transition model, individuals may be born either in urban or rural areas.

- ${}_nd_x^{ij}$ = number of transitions from state i to state j occurring between ages x and $x+n$ among cohort members

For example, in the marriage model described above, we have four different types of transitions:

${}_nd_x^{UM}$ = number of transitions from unmarried to married (i.e., number of marriages) among cohort members aged x to $x+n$;
${}_nd_x^{UD}$ = number of transitions from 'unmarried' to 'dead' (i.e., number of deaths) among unmarried cohort members aged x to $x+n$;
${}_nd_x^{MU}$ = number of transitions from 'married' to 'unmarried' (i.e., through divorce or widowhood) among cohort members aged x to $x+n$; and
${}_nd_x^{MD}$ = number of transitions from married to dead (i.e., number of deaths) among married cohort members aged x to $x+n$.

In a multistate life table, survivors and transitions are related with one another in the following fashion (using the marriage model as an example):

$$l_{x+n}{}^U = l_x{}^U - {}_nd_x{}^{UM} - {}_nd_x{}^{UD} + {}_nd_x{}^{MU}$$

$$l_{x+n}{}^M = l_x{}^M - {}_nd_x{}^{MU} - {}_nd_x{}^{MD} + {}_nd_x{}^{UM}$$

- ${}_nq_x^{ij}$ = probability that an individual who is in state i at age x will be in state j at age $x+n$.

If it can be assumed that only one transition is possible between x and $x+n$, this probability is related to other life table quantities through the following equation:

$${}_nq_x{}^{ij} = {}_nd_x{}^{ij}/l_x{}^i$$

In the marriage example, there are four possible transition probabilities:

${}_nq_x{}^{UM}$ = probability that an *unmarried* individual aged x will be *married* at age $x+n$;
${}_nq_x{}^{UD}$ = probability that an *unmarried* individual aged x will *die* by age $x+n$;
${}_nq_x{}^{MU}$ = probability that a *married* individual aged x will be *unmarried* at age $x+n$; and
${}_nq_x{}^{MD}$ = probability that a *married* individual aged x will *die* by age $x+n$.

- ${}_nL_x{}^i$ = number of person-years lived in state i between age x and $x+n$ by individuals in the cohort

Obviously, person-years can only be lived in a 'living' state, so in the marriage example, there are only two types of person-years:

${}_nL_x{}^U$ = person-years lived in the unmarried state between age x and $x+n$ by individuals in the cohort; and
${}_nL_x{}^M$ = person-years lived in the married state between age x and $x+n$ by individuals in the cohort.

Note that ${}_nL_x{}^U + {}_nL_x{}^M = {}_nL_x$, i.e., the number of person-years lived between x and $x+n$ by all members of the cohort, regardless of marital status.

- ${}_nm_x^{ij}$ = transition rate from state i to state j between age x and $x+n$

This transition rate is related to other life table functions through the following equation:

$${}_nm_x{}^{ij} = {}_nd_x{}^{ij}/{}_nL_x{}^i$$

This is a classic occurrence/exposure rate with events (transitions) in the numerator and person-years of exposure in the denominator. Since only individuals in state i are at risk of experiencing a transition from state i to state j, the exposure term in the denominator is limited to person-years lived in state i. In the marriage example, as in the case of transition probabilities, each age group has four possible transition rates: ${}_nm_x{}^{UM}$; ${}_nm_x{}^{UD}$; ${}_nm_x{}^{MU}$; and ${}_nm_x{}^{MD}$.

- $T_x{}^i$ = number of person-years lived in state i above age x by individuals in the cohort

This quantity corresponds to the sum of ${}_nL_x{}^i$ for ages x and higher. In the marriage example, there will be two types of $T_x{}^i$ values:

$T_x{}^U$ = number of person-years lived above age x in the *unmarried* state; and
$T_x{}^M$ = number of person-years lived above age x in the *married* state.

Note that $T_x{}^U + T_x{}^M = T_x$, the number of person-years lived above age x by all members of the cohort.

- $e_x{}^i$ = life expectancy at age x in state i = number of years that an individual aged x can expect to live in state i

These life expectancies are related to other life table functions through the following equation:

$$e_x{}^i = T_x{}^i/l_x$$

These life expectancies are called 'unconditional' life expectancies, because the denominator includes all survivors at age x (l_x), regardless of state occupancy at age x.

In the marriage example, there will be two types of unconditional life expectancies:

e_x^U = number of years that an individual aged x can expect to live in the *unmarried* state; and
e_x^M = number of years that an individual aged x can expect to live in the *married* state.

Note that $e_x^U + e_x^M = e_x$. That is, a multistate life table apportions the classic life expectancy, e_x, among different states. In turn, state-specific unconditional life expectancies add up to the classic life expectancy.

- T_x^{ij} = number of person-years lived in state j above age x by cohort members who are in state i at age x

Typically, in a multistate transition model, future state occupancy depends highly on the state that an individual occupies at age x. For example, an individual who is married at age 50 cannot expect to spend the same number of years above 50 in the married state as an individual who is not married at age 50. When calculating person-years lived above age x, it is thus useful to calculate person-years lived above age x in a given state conditional on state occupancy at age x. In the marriage example, there will be four types of conditional T_x^{ij} values:

T_x^{UU} = number of person-years lived above age x in the *unmarried* state by individuals who are *unmarried* at age x;
T_x^{UM} = number of person-years lived above age x in the *married* state by individuals who are *unmarried* at age x;
T_x^{MU} = number of person-years lived above age x in the *unmarried* state by individuals who are *married* at age x; and
T_x^{MM} = number of person-years lived above age x in the *married* state by individuals who are *married* at age x.

Note that $T_x^{UU} + T_x^{MU} = T_x^U$ defined earlier. Likewise, $T_x^{UM} + T_x^{MM} = T_x^M$.

These person-years conditional on state occupancy at age x allow one to calculate a second kind of life expectancies, called 'conditional' life expectancies:

- e_x^{ij} = life expectancy at age x in state j, for individuals who are in state i at age x.

These life expectancies are related to other life table functions through the following equation:

$$e_x^{ij} = T_x^{ij}/l_x^i$$

In the marriage example, there are four types of conditional life expectancies:

e_x^{UU} = number of years that an individual who is *unmarried* at age x can expect to live in the *unmarried* state;
e_x^{UM} = number of years that an individual who is *unmarried* at age x can expect to live in the *married* state;
e_x^{MU} = number of years that an individual who is *married* at age x can expect to live in the *unmarried* state; and
e_x^{MM} = number of years that an individual who is *married* at age x can expect to live in the *married* state.

Note that unconditional life expectancies are weighted averages of conditional life expectancies, with the weights being the proportion of survivors by state at age x. For example, in the marriage example

$$e_x^U = l_x^U/l_x \cdot e_x^{UU} + l_x^M/l_x \cdot e_x^{MU}$$

In a multistate life table, the most important quantities are ${}_nq_x^{ij}$ or ${}_nm_x^{ij}$, which summarize the pattern of transitions between states, as well as e_x^i or e_x^{ij}, which summarize mean duration of state occupancy above age x.

Multistate Life Tables in a Period

If individual-level cohort information is available, life expectancies can be readily observed without resorting to any kind of complex computational approach. Person-years spent in each state by cohort members can be directly observed and summed across individuals. Life expectancies in a given state are simply mean person-years lived in a given state, conditional or not on earlier state occupancy.

As a simple numerical example, let us assume that the following information is available on two individuals born the same day: individual #1 died at age 80 with 30 years spent in the unmarried and 50 years spent in the married state, while individual #2 died at age 60 with 46 years spent in the unmarried state and 14 years spent in the married state. It can then be readily estimated that the life expectancy at birth for this cohort of two individuals is $(80+60)/2 = 70$ years, with an unconditional life expectancy at birth in the unmarried state of $(30+46)/2 = 38$ years and an unconditional life expectancy at birth in the married state of $(50+14)/2 = 32$ years. Since in this model all individuals are born in the unmarried state, life expectancies at birth conditional on being unmarried at birth (e_0^{UU} and e_0^{UM}) are equal to the unconditional life expectancies (e_0^U and e_0^M, respectively) and the life expectancies at birth conditional on being married at birth (e_0^{MU} and e_0^{MM}) are undefined. With additional information on ages at transition for cohort members, life expectancies at ages above 0, conditional or unconditional, can also be readily observed without using information on transition rates or probabilities.

Most often, however, analysts are interested in estimating multistate life tables for a period. In a period multistate life table, age-specific transition rates are observed for a given year or period, and the analyst is interested in examining what would happen to a cohort of individuals if they were exposed at each age to the transition rates observed during the given period. This is the classic synthetic cohort approach that is used whenever constructing a classic period life table.

When constructing a period life table, however, person-years and life expectancies by state cannot be readily observed, because the synthetic cohort is not a real cohort and thus cannot be tracked over time. One classic strategy for calculating a period multistate life table starts from calculating transition rates, which can be estimated from period data if information on transitions and population at risk is available:

$${}_nm_x^{ij} \approx {}_nD_x^{ij}/{}_nN_x^i$$

where ${}_nD_x^{ij}$ are observed transitions from state i to state j between age x and $x+n$ during a given year, and where ${}_nN_x^i$ is the midyear population in state i between ages x and $x+n$, used as an estimate of the number of person-years of exposure in state i between ages x and $x+n$ during a given year.

Using these transition rates, a synthetic cohort can then be simulated and corresponding person-years and life expectancies can be estimated. Like in the case of a classic life table construction, a key aspect of period multistate life table construction consists of performing what amounts to a rate-to-probability conversion, so that the synthetic cohort can be simulated. This involves solving a system of equations, with assumptions about how transitions are distributed within the age interval. One classic assumption is to assume that the number of state-specific survivors varies linearly between age x and $x+n$. In the marriage example, this assumption would produce the following system of equations (one system for each age group):

1. $l_{x+n}^{U} = l_x^{U} - {}_nd_x^{UM} - {}_nd_x^{UD} + {}_nd_x^{MU}$
2. $l_{x+n}^{M} = l_x^{M} - {}_nd_x^{MU} - {}_nd_x^{MD} + {}_nd_x^{UM}$
3. ${}_nd_x^{UM} = {}_nm_x^{UM} \cdot {}_nL_x^{U}$
4. ${}_nd_x^{UD} = {}_nm_x^{UD} \cdot {}_nL_x^{U}$
5. ${}_nd_x^{MU} = {}_nm_x^{MU} \cdot {}_nL_x^{M}$
6. ${}_nd_x^{MD} = {}_nm_x^{MD} \cdot {}_nL_x^{M}$
7. ${}_nL_x^{U} = n/2 \cdot (l_x^{U} + l_{x+n}^{U})$
8. ${}_nL_x^{M} = n/2 \cdot (l_x^{M} + l_{x+n}^{M})$

In this system of eight equations, the only known quantities are the following: ${}_nm_x^{UM}$, ${}_nm_x^{UD}$, ${}_nm_x^{MU}$, and ${}_nm_x^{MD}$. In total, there are eight equations and eight unknowns, which is solvable. The algebraic solution for the case of two living states can be found in Schoen (1988a). If there are more than two living states, the system of equations will be more complex and can be solved using matrix algebra (Palloni, 2001).

Like in any life table construction, the rate-to-probability conversion involves certain assumptions. In the example above, the assumption is that the number of survivors in state i (l_x^i) varies linearly between ages x and $x+n$. The most common alternative is to assume that transition rates, in continuous terms, are constant between ages x and $x+n$ (Schoen, 1988a).

Once the system of equations has been solved, the synthetic cohort can be simulated. One simply needs to choose an arbitrary radix for the life table (l_0), and apportion this radix by state (l_0^i). In many cases, the distribution by state of individuals aged 0 is theoretically implicit. For example, in the marriage model, it is assumed that $l_0^U = l_0$. In some cases, however, the analyst needs to decide how to distribute individuals aged 0 by state. A common option is to use actual distributions of births by state as recently observed in the population. We will see later that in multistate models that involve reproduction, the distribution of births by state is entirely determined by the model, so no arbitrary choice needs to be made. Once values of l_0^{i} are chosen, state-specific survivors can be simulated as if they were exposed to the observed period transition rates, and the different life expectancies described above can be calculated.

Note that the construction of a multistate life table typically makes an assumption of homogeneity: all the individuals in state i at age x are assumed to have the same probability of experiencing a transition. That is, transition probabilities depend only on age and current state (a setup also known as a first-order Markov chain in the statistics literature). The past history of state occupancy is not taken into account. This assumption is potentially problematic for period life tables if indeed duration in a state influences transition rates in addition to age.

Statistical Approaches to Estimating Multistate Life Tables

The life table approach discussed above assumes that transition rates can be estimated with precision for well-defined age groups and time periods using survey data or exhaustive population information. In many cases, however, this goal is difficult to attain, especially when dealing with survey data. Transitions of interest to demographers (such as death, marriage, disability, etc.) tend to be relatively rare events. Sample sizes in available surveys are often too small to produce estimates of transition rates that are precise enough for direct use in life table construction. Moreover, longitudinal surveys typically have varying interview dates and individuals are observed at irregular intervals, which create additional difficulties for the calculation of well-defined rates or probabilities. Finally, the approach discussed above is deterministic and does not readily allow statistical inference for transition rates or life expectancies.

The typical data configuration for the statistical estimation of transition rates on the basis of longitudinal data is as follows: a sampled individual is observed at a first interview date, during which information is gathered about age and current state. Later, the individual is reinterviewed, and current state is updated. If the individual has changed states by the time of the second interview, he/she may be asked about the date at which his/her status changed. If the individual died between the two interview dates, information about the exact date of death is sometimes recorded. Sometimes information at a third interview may be available, but some individuals may be missing information at one of the three interviews. Statistical approaches for the estimation of a multistate transition model will use information about sampled individuals with a range of ages at a first interview (for which the exact date may vary across individuals), and then estimate a set of period age-specific transition rates that best agree with the observed patterns of transitions among sampled individuals.

There are many different statistical approaches to estimating period age-specific transitions rates from longitudinal survey data (Willekens and Putter, 2014). One commonly used approach is called Interpolated Markov Chains (IMaCh) and is available as a software (Lièvre et al., 2003; Brouard and Lièvre, 2009). IMaCh is tailored to the estimation of health expectancies (with a transition model involving three states: healthy; disabled; and dead) and makes parametric assumptions about how transition rates vary with age. Specifically, IMaCh assumes that the partial odds of monthly transition probabilities follow a log-linear function of age (Laditka and Wolf, 1998). Using a maximum likelihood approach, the software produces a set of parameters for the log-linear functions that best agrees with the set of observed individual transitions. The estimated transition probabilities are then used to estimate of complete multistate life table, including state-specific life expectancies. Confidence intervals around life expectancies are calculated using the Delta method.

Another software, called SPACE, was published in 2010 by Cai et al. (Cai et al., 2010). One important difference with IMaCh is that life table outputs are calculated by resorting to

micro-simulation. Once transition probabilities are estimated, individual life histories are simulated and then aggregated to produce mean values of the output quantities. Confidence intervals around mean output values are calculated using bootstrapping. The SPACE approach is being increasingly used for the estimation of health expectancies (Payne et al., 2013).

Multistate Population Models

Multistate Stationary Populations

If it can be assumed that there is a constant annual number of births by state (B^i), and that age-specific transition rates are constant over time, then the corresponding population is a multistate stationary population. Like a classic stationary population, this population will have a constant size and constant state and age distribution. Moreover, the population distribution by state will be proportional to the ${}_nL_x{}^i$ column of the corresponding multistate life table:

$$ {}_nN_x^i/N^i = {}_nL_x^i/T_0{}^i, $$

where ${}_nN_x{}^i$ is the population aged x to $x+n$ in state i, and where N^i is the total population in state i; and

$$ N^i/N = T_x{}^i/T_0, $$

where N is the total population size for all states combined.

Thus, in a stationary multistate population, unconditional life expectancies (e_0^i) can be readily calculated by applying the proportion of the total population that is in state i to the overall life expectancy: $e_0^i = e_0 \cdot (N^i/N)$. In the marriage example, if the multistate model is stationary with an overall life expectancy of 75 years and with 40% of the total population in the 'married' state, then the number of years that a newborn can expect to live in the married state if $75 \cdot 0.4 = 30$ years.

This stationary model is a special case of a more general population model in which transition rates are constant over time, and in which the number of births, while varying over time, has a constant distribution by state. That is, $B^i(t)/B(t)$ is constant over time t. This is a useful model, because in many cases, $B^i(t)/B(t)$ is constant over time due to the very nature of the multistate process. In the marriage model, for example, regardless of variations in the number of births each year, 100% of births occur in the unmarried state every year.

In this less restrictive population model, N^i/N is not equal to $T_0{}^i/T_0$, like in the case of a stationary population. However, ${}_nN_x^i/{}_nN_x = {}_nL_x^i/{}_nL_x$. This provides a useful shortcut for calculating a multistate life table in the absence of information on transitions. One simply needs to first calculate an ${}_nL_x$ column for all states combined (i.e., as in a classic life table). ${}_nL_x{}^i$ can then be calculated by applying at each age the observed proportion of the age-specific population that is in state i, using for example, information from a census or a cross-sectional survey:

$$ {}_nL_x^i = {}_nL_x \cdot {}_nN_x^i/{}_nN_x $$

This approach is commonly used for estimating disability-free life expectancy in the absence of information on transitions in-and-out of disability (Cambois et al., 1999). This method, called the Sullivan method (Sullivan, 1971), assumes that: (1) age-specific transition rates in the multistate system have been constant over time; and (2) the proportion of births by disability status has been constant over time. While the second assumption is not problematic (the proportion of individuals who are free of disability at birth is close to 100% and can be assumed to be constant over time), the assumption of constant transition rates can be problematic in populations that have experienced fast mortality declines and changes in the incidence of disability (Rogers et al., 1990; Barendregt et al., 1994, 1997; Lièvre et al., 2003).

Multistate Stable Populations

The multistate stable population model is a model which includes entry into the population through reproduction, in addition to attrition out of the population through mortality (Schoen, 1988a,b). This model makes the following assumptions:

- Age-specific transition rates are constant over time;
- Age-specific fertility rates by state are constant over time.

If these assumptions hold, then a multistate stable population emerges with the following features:

- The proportionate distribution of the population by age and state is constant over time;
- The overall growth rate of the population is constant over time.

Multistate stable populations have the same property of ergodicity as classic stable populations. This implies that any population with multiple states has an underlying 'stable-equivalent' multistate population with an intrinsic growth rate and an intrinsic distribution of the population by age and state. Although it does not include age, the urban/rural residence model presented in **Figure 1** illustrates this property of ergodicity and the concept of intrinsic parameters. In this example, the observed set of rates of natural increase and out-migration produces an 'intrinsic' proportion of the population living in urban areas of 69.7%.

Multistate stable populations have been used in a number of applications. One classic application shows that fertility differentials by IQ levels (with low-IQ persons having above-average fertility), rather than generating decreases in the population's mean IQ level in the long term, generate constant mean IQ levels in the long term that may or may not be lower than the population's current mean IQ level (Preston and Campbell, 1993).

Abstract

In discriminant analysis, there are a number of distinct groups, and each entity under consideration is assumed to belong to one of them. Typically, the problem is to assign an unclassified entity to its group of origin on the basis of a feature vector, which consists of a number of measurements made on the entity. In order to construct an allocation rule for this assignment, there are so-called training data consisting of feature vectors on a number of entities that are classified with respect to the groups.

Introduction

The need for classification arises in most scientific pursuits. Typically, there is interest in 'classifying' an entity, say, an individual or object, on the basis of some characteristics (feature variables) measured on the entity. This classification is usually undertaken in two main contexts. In the first context, there is a finite number, say g, of predefined distinct populations, categories, classes, or groups, and the entity to be classified is assumed to belong to one (and only one) of these g possible groups. In order to assist with the construction of a classification rule for this purpose, there are usually available so-called training data from each group; that is, these training data comprise the features measured on some entities that are classified with respect to the g underlying groups. In statistical terminology, this classification process is referred to as *discriminant analysis*, while it is referred to as *supervised learning* or *learning with a teacher* in pattern recognition and machine learning.

In the second context, the classification of some entities is undertaken on the basis of their feature data in the absence of any prior knowledge on the existence of distinct groups. In this case, the primary purpose of the classification is to put the entities into a number of clusters so that entities within a cluster tend to have more similar features than those in different clusters. In statistics, this process is referred to as *cluster analysis*. In this article, attention is confined to discriminant analysis.

Discriminant Analysis

It is supposed that an entity belongs to one of g possible groups, denoted by $G_1, \ldots, G_g$, and that there is a (feature) vector $\boldsymbol{x}$ containing p variables that can be measured on the entity. The group-membership of the entity is denoted by the categorical variable z, where $z = i$ implies that the entity belongs to G_i $(i = 1, \ldots, g)$. In this notation, the topic of discriminant analysis may be viewed as being concerned with the relationship between z and the feature vector $\boldsymbol{x}$. Within this broad topic, there is a spectrum of problems that corresponds to the inference-decision spectrum in statistical methodology. At the decision end of the scale, the group-membership of the entity is unknown and the intent is to make an outright assignment of the entity to one of the g possible groups on the basis of $\boldsymbol{x}$. That is, in terms of the present notation, the problem is to estimate z solely on the basis of $\boldsymbol{x}$. An example in which an outright assignment is required concerns the rejection or acceptance of loan applicants by a financial institution. For this decision problem there are two groups with say G_1, referring to applicants who will service their loans satisfactorily, and G_2 to those who do not. The feature vector $\boldsymbol{x}$ for an applicant contains information such as age, income, and marital status. A rule based on $\mathbf{x}$ for allocating an applicant to either G_1 or G_2 (i.e., either accepting or rejecting the loan application) can be formed from an analysis of the feature vectors of past applicants from each of the two groups.

At the other extreme end of the spectrum, no assignment of the entity to one of the possible groups is intended. Rather the problem is to draw inferences about the relationship between z and the feature variables in $\boldsymbol{x}$. An experiment might be designed with the specific aim of providing insight into the predictive structure of the feature variables. For example, a political scientist may wish to determine the socioeconomic factors that have the most influence on the voting patterns of a population of voters. Between these extremes lie most of the everyday situations in which discriminant analysis is applied (Hand, 1997; McLachlan, 1992; Ripley, 1996).

Allocation Rules

Let $r(\boldsymbol{x})$ denote an allocation rule, where $r(\boldsymbol{x}) = i$ implies that an entity with feature vector $\boldsymbol{x}$ is to be assigned to the ith group G_i. The allocation rates associated with this rule $r(\boldsymbol{x})$ are denoted by $e_{ij}(r)$, where $e_{ij}(r)$ is the probability that a randomly chosen entity from G_i is allocated to G_j $(i, j = 1, \ldots, g)$. For a diagnostic test using the rule $r(\boldsymbol{x})$ in the context where G_1 denotes the absence of a disease or condition and G_2 its presence, the error rate $e_{12}(r)$ corresponds to the probability of a false positive, while $e_{21}(r)$ is the probability of a false negative. The correct allocation rates $e_{22}(r)$ and $e_{11}(r)$ are known as the sensitivity and specificity, respectively, of the diagnostic test.

Decision theory provides a convenient framework for the construction of discriminant rules in the situation where an outright allocation of an unclassified entity is required. For given $\boldsymbol{x}$, the expected loss or risk for allocation performed on the basis of the rule $r(\boldsymbol{x})$ is equal to $\sum_{i=1}^{g} \tau_i(\boldsymbol{x}) Q[i, r(\boldsymbol{x})]$ where,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.42150-1

for any u and v, $Q(u, v) = 0$ for $u = v$ and 1 for $u \neq v$, and where $\tau_i(\boldsymbol{x})$ is the posterior probability that the entity belongs to G_i which, by Bayes' theorem, can be expressed as

$$\tau_i(\boldsymbol{x}) = \pi_i f_i(\boldsymbol{x}) / f(\boldsymbol{x}) \quad (i = 1, \ldots, g) \qquad [1]$$

In [1], $f_i(\boldsymbol{x})$ denotes the density of the feature vector $\boldsymbol{X}$ in group G_i, $f(\boldsymbol{x}) = \sum_{i=1}^{g} \pi_i f_i(\boldsymbol{x})$ is the unconditional density of $\mathbf{X}$, and π_i denotes the prior probability that the entity belongs to G_i. The costs of misallocation have been assumed to be zero here for a correct allocation and unity for a misallocation from one group to another.

An optimal rule of allocation can be defined by taking it to be the one that minimizes the conditional risk at each value $\boldsymbol{x}$ of the feature vector. In decision-theory language, such a rule is said to be a Bayes' rule. It follows that the Bayes' rule $r_o(\boldsymbol{x})$ assigns the entity to the group to which it has the highest posterior probability of belonging under the specified utility function.

Sample-Based Allocation Rules

In practice, the group-conditional densities $f_i(\boldsymbol{x})$ are usually unknown. A basic assumption in discriminant analysis is that in order to estimate the unknown group-conditional densities there are entities of known origin on which the feature vector $\boldsymbol{X}$ has been recorded for each. These data are referred to in the literature as either the initial, reference, design, training, or learning data.

The initial approach to the problem of forming a sample discriminant rule, and indeed to discriminant analysis in its modern guise, was by Fisher (1936). In the context of $g = 2$ groups, he proposed that an entity with feature vector $\boldsymbol{x}$ be assigned on the basis of the linear discriminant function $a^T\boldsymbol{x}$, where a maximizes an index of separation between the two groups. The index was defined to be the magnitude of the difference between the group-sample means of $a^T\mathbf{x}$ normalized by the pooled sample estimate of its assumed common variance within a group.

To consider the formation of sample rules in general, we need to consider the sampling designs under which the training data $\boldsymbol{T}$ have been realized. There are two major schemes: joint or mixture sampling and z-conditional or separate sampling. They correspond respectively to sampling from the joint distribution of $\boldsymbol{Y} = (\boldsymbol{X}^T, \boldsymbol{Z}^T)^T$ and to sampling from the distribution of $\boldsymbol{X}$ conditional on z. The first design applies to the situation where the feature vector and group of origin are recorded on each of n entities drawn from a mixture of the possible groups. Mixture sampling is common in prospective studies and diagnostic situations. In a prospective study design, a sample of individuals is followed and their responses recorded. With separate sampling in practice, the feature vectors are observed for a sample of n_i entities taken separately from each group G_i, and so it is appropriate to retrospective studies.

An obvious way of forming a sample-based allocation rule $r(\boldsymbol{x}; t)$ is to take it to be an estimated version of the Bayes' rule $r_o(\boldsymbol{x})$, where the posterior probabilities of group-membership $\tau_i(\boldsymbol{x})$ are replaced by some estimates $\widehat{\tau}_i(\mathbf{x}; t)$ formed from the training data t. A common approach, referred to as the sampling approach, is to use the Bayes' formula [1] to formulate the $\tau_i(\boldsymbol{x})$ through the group-conditional densities $f_i(\boldsymbol{x})$. With the fully parametric approach to this problem, the group-conditional densities $f_i(\boldsymbol{x})$ are assumed to have specified functional forms except for a finite number of parameters to be estimated. A commonly used parametric family for the $f_i(\boldsymbol{x})$ for continuous feature data is the normal with either a linear or quadratic rule in $\mathbf{x}$ being obtained depending on whether the group-covariance matrices are taken to be equal or unequal. A compromise between linear and quadratic discriminant analyses is regularized discriminant analysis (Friedman, 1989).

There is also the direct approach (the diagnostic paradigm) to the estimation of the $\tau_i(\mathbf{x})$, using either nonparametric estimates as with nearest neighbor methods or parametric estimates via the logistic model. With the latter approach, it is the ratios of the group-conditional densities that are being modeled. The fundamental assumption of the logistic approach is that these ratios are linear, which is equivalent to taking the log(posterior) odds to be linear. The linearity here is not necessarily in the basic variables; transforms of these may be taken.

Another method for the direct modeling of the group-posterior probabilities is to use neural networks (Bishop, 1995), which have been coming under increasing attention by statisticians; see Ripley (1996). For example, with a two-layered feedforward neural network with m hidden units in the case of $g = 2$ groups, $\tau_1(\boldsymbol{x})$ is modeled as $\tau_1(\boldsymbol{x}) = \phi(w_{20} + \sum_{k=1}^{m} w_{2k} u_k)$ where $u_k = \phi(w_{10k} + \sum_{h=1}^{p} w_{1hk}(\boldsymbol{x})_h)$ is the value of the kth hidden unit, and the w_{1hk}, w_{2k} are parameters known as weights; $\phi(u)$ is the so-called activation function, often taken to be the sigmoid function, $\phi(u) = 1/1(+e^{-u})$. Neural networks are fitted mostly using *back propagation*, which is essentially gradient descent using the chain rule, but the EM algorithm has been used too recently. By the inclusion of an appropriate number of hidden units in the hidden layer (or layers), neural networks can handle nonlinear boundaries between the groups.

An advantage of the logistic and neural network-based rules is that they can handle discrete feature variables. Also, the multinomial distribution can be used to model the group-conditional probabilities for discrete feature variables. But unless the number m of multinomial cells is very small or the sample size n is extremely large, some of the cells will contain no observations and so some form of smoothing has to be applied. The nonparametric estimates of the multinomial cell probabilities under the assumption of independence of all the p feature variables may impose too high a degree of smoothing on the multinomial estimates. Hence, the aim of smoothing is to provide a degree of smoothing intermediate to that obtained under the extremes of the full multinomial and independence models.

To illustrate the construction of sample-based allocation rules, we consider the construction of a discriminant rule for the problem of assessing loan applications, as mentioned in Section Discriminant Analysis. Here the applicant for a loan is a company and the feature vector contains information on its key financial characteristics. For the purposes of our illustration, we consider the case where there are $p = 2$ feature variables that are the first two principal components of three

financial ratios concerning the debt, liquid assets, and working capital of a company. In Figure 1, we have plotted the boundary

$$\hat{\tau}_1(\boldsymbol{x}_j; t) = \hat{\tau}_2(\boldsymbol{x}_j; t)$$

for the sample version of the Bayes' rule (the sample linear discriminant rule) formed under the assumption that the feature vector has a bivariate normal distribution with a common group-covariance matrix in each of the two groups G_1 and G_2, corresponding to good (satisfactorily serviced) and bad (unsatisfactorily serviced) loans. It can be seen that the overall error rate of this rule reapplied to the training data (its apparent error rate) is not as low as that of the quadratic rule formed without the restriction of a common group-conditional covariance matrix for the feature vector $\boldsymbol{X}$. With its curved boundary, the quadratic rule misallocates only four (all bad) loans. One should be mindful, however, that the apparent error rate provides an optimistic assessment of the accuracy of a discriminant rule when it is applied to data not in the training set (see the next section). We have also plotted in Figure 1 the boundary of the rule obtained by modeling the distribution of the feature vector $\boldsymbol{X}$ by a two-component normal mixture, which results in the misallocation of one bad loan at the expense of misallocating two good loans. The latter rule is an example of a more flexible approach to classification than that based on the assumption of normality for each of the group-conditional distributions, as to be considered now.

The reader is referred to Geisser (1982) for a Bayesian approach to the formation of sample-based rules whereby prior distributions are adopted for the unknown parameters in the postulated model for the class-conditional distributions.

In some applications, the training data are only partially classified with respect to the classes, as considered, for example, in McLachlan (1975); see also McLachlan (1992: Section 2.7) and McLachlan and Peel (2000: Section 2.19). A case study may be found in McLachlan and Gordon (1989).

Figure 1 Boundaries of linear rule (solid line), quadratic rule (dashed line), and mixture model-based rule (dotted line); crosses and circles denote good and bad loans, respectively.

Flexible Discriminant Rules

A common nonparametric approach to discriminant analysis uses the kernel method to estimate the group-conditional densities $f_i(\boldsymbol{x})$ in forming an estimate of the Bayes' rule. More recently, use has been made of finite mixture models, mainly normal mixtures, to provide flexible rules of discrimination (Hastie and Tibshirani, 1996). Mixture models provide an extremely flexible way of modeling a density function (McLachlan and Basford, 1988; McLachlan and Peel, 2000) and can be fitted in a straightforward manner via the EM algorithm (McLachlan et al., 1999; McLachlan and Krishnan, 2008). Among other work on flexible discrimination, there is the FDA (flexible discriminant analysis) approach based on nonparametric regression (see Hastie and Tibshirani, 1996). The generic version of FDA based on smoothing splines proceeds by expanding the predictors in a large (adaptively selected) basis set, and then performing a penalized discriminant analysis in the enlarged space using a linear discriminant or a normal mixture model-based rule. The class of nonlinear regression methods that can be used include additive models, the multivariate adaptive regression spline (MARS) model, projection pursuit regression, and neural networks. In machine learning, there has been increasing attention in the case of two groups given to nonlinear rules based on the foundations of support vector machines, as developed by Vapnik (2000). With this approach, the initial feature space is mapped into a higher dimensional space by choosing a nonlinear mapping and then choosing an optimal separate hyperplane in the enlarged feature space.

A rather different approach to the allocation problem as considered up to now is to portray the rule in terms of a binary tree. The tree provides a hierarchical representation of the feature space. An allocation is effected by proceeding down the appropriate branches of the tree. The Classification and Regression Tree (CART) methodology of Breiman et al. (1984) has contributed significantly to the growing popularity of tree classifiers; see also the C4.5 decision-tree learning algorithm of Quinlan (1993). In the context of tree classifiers in particular, there has been growing interest in the use of boosting, which is one of the most important recent developments in classification methodology. Algorithms like the Adaboost algorithm of Freund and Schapire (1996) and the bagging algorithm of Breiman (1996) can often improve performance of unstable classifiers like trees or neural nets by sequentially applying them to reweighted versions of the training data and taking a weighted majority vote of the sequence of classifiers so formed. The test error of the weighted classifier usually does not increase as its size increases, and often is observed to decrease even after the training error reaches zero. Friedman et al. (2001) have exhibited the link of boosting to statistical ideas on additive fitting.

An excellent summary of available software and algorithms for discriminant analysis has been given by the Panel on Discriminant Analysis, Classification and Clustering (1989); see also Huberty (1994) and Michie et al. (1994).

Feature Selection

$$\mathbf{S} = \sum_{i=1}^{g} \sum_{j=1}^{n} z_{ij} \left(y_j - \bar{y}_i \right) \left(y_j - \bar{y}_i \right)^T \Big/ \left(n - g \right) \qquad [2]$$

There is a vast literature on variable selection in discriminant analysis. Some of the methods are applicable only if the number of variables p is well below the sample size n; see, for example, Maugis et al. (2011) in which a general methodology is proposed for selecting predictors for normal class-conditional distributions. When the dimension p is large, some of the commonly used classifiers might be unreliable or not able to be formed in the first instance. For example, Fisher's linear discriminant function requires taking the inverse of the pooled within-class covariance matrix $\mathbf{S}$ as defined by eqn [2]. This is only possible if $p \leq n - 2$. One way to avoid this is to take the class-covariance matrices to be diagonal; that is, to use what is termed as 'naive Bayes' (Hand and Yu, 2001). Bickel and Levina (2004) show that this latter rule can be used effectively in such situations. More recently, Professor Fan and colleagues have demonstrated that if p is ultra high compared to n, then the naive Bayes rule can perform as bad as random guessing in certain situations where the signal-to-noise ratio is weak due to the noise accumulation in the estimation of the class means; see Fan and Lv (2008, 2010) and the references therein. The L_1 or Lasso penalty proposed in Tibshirani (1996) is often applied to penalize the likelihood function in situations where p is very large; see Efron et al. (2004). Recently, Witten and Tibshirani (2011) have proposed a penalized form of Fisher's linear discriminant function by imposing a penalty on the discriminant vectors.

One commonly used method of feature selection is based on the ratio of the between-class sum of squares to the within-class sum of squares. There are other methods such as selecting the variables on the relative size of their weights in the linear kernel in the formation of the support vector machine. Guyon et al. (2002) proposed that the feature variables be selected according to a backward elimination process, which they call recursive feature elimination (RFE). It starts by considering all available features. Each step consists in ranking the features according to the order of magnitude of their associated coefficients (weights) β_i, and then discarding the bottom-ranked variables. The SVM is then refitted to the remaining variables, which are then reranked according to their new weights. Again, the bottom-ranked variables are discarded, and so on. The process can be refined at the expense of greater computational time by deleting fewer variables on each step. One suggested procedure is to apply RFE by removing chunks of features in the first few iterations and then removing one feature at a time once the feature set size reaches a few hundreds.

Projection methods are also very popular for reducing the dimension of the feature space and include matrix factorization (MF) with orthogonality constraints as in principal component analysis (PCA) and singular-value decomposition (SVD) and matrix factorization without orthogonality constraints as in general MF (Nikulin et al., 2011). These projection methods can be implemented in conjunction with penalty constraints as considered by Witten et al. (2009) There is also partial least squares (PLS) as adopted, for example, by Nguyen and Rocke (2002).

There is much ongoing research in the area of variable selection in discriminant and cluster analyses in the case where p is much greater than n. This is because traditional methods are faced with formidable challenges as exemplified by the data piling problems in high-dimensional space observed in Hall et al. (2005); see also Fan and Lv (2008, 2010); Fan et al. (2009). The impact of high dimensionality for distance-based classifiers has been studied by Hall et al. (2008).

Error-Rate Estimation

A guide to the performance of a given discriminant rule can be obtained by applying it to the training from which it was formed and noting the proportion of these observations misallocated (the apparent rate). However, it is well known that the apparent error rate gives too optimistic a view on how the rule might perform on future cases; see McLachlan (1992: Chapter 10) for an account of error-rate estimation. One way of correcting for this bias is to use cross-validation, but it produces an estimate that often is more highly variable than the apparent error rate. This led Efron (1983) to consider his so-called 0.632 estimator, which is a weighted sum of the apparent error rate and the bootstrap error rate at an original data point not in the training set t. Efron (1983) showed that the latter error rate is almost the same as the twofold (half-sample) cross-validated error rate, which previously McLachlan (1977a) had weighted with the apparent error rate in proportions w and $(1 - w)$ with the apparent error rate in order to reduce its bias. Under certain conditions in the case of normality, it was shown that the value of w ranged from 0.6 to 0.7 in order to achieve asymptotically zero bias. Thus, it is very similar to the 0.632 estimator. Efron and Tibshirani (1997) proposed an improved version of the 0.632 estimator known as the 0.632+ estimator. The bootstrap methodology can be used also to estimate the variability in the errors and in other quantities of interest, such as the estimated parameters in the form of the estimated rule.

Conclusion

Discriminant analysis is concerned with the construction of allocation rules for the assignment of unclassified entities to distinct groups in the situation where there are data on entities of known group of origin (training data). In the past, linear rules such as those based on Fisher's linear discriminant function were commonly used in practice. In recent times, with the wide availability of high-speed computers, there has been increasing attention given to the development of more complex nonlinear rules such as those based on flexible parametric models, neural networks, support vector machines, and classification trees.

Abstract

Correspondence models are a special class of statistical models for the association between categorical variables. The specific parametric structure of such models is based, as in the common (descriptive) correspondence analysis, on the canonical form of joint discrete distributions. Bivariate correspondence models are considered first, based on a simple canonical form involving canonical correlations. Such models are discussed in great detail, where interpretation of parameters and inferential aspects receive special attention. Joint multivariate distributions do not have a universal canonical form, and correspondence models for the multivariate case require therefore a modified methodology. Such methodology is presented next, in which discussion on multivariate correspondence models is divided into two cases. One case is where the variables can be partitioned into two natural groups of variables (response and explanatory, say); the second case is where all variables are treated on an equal footing. Correspondence models for three variables are discussed in detail as a special case from which extensions to a higher number of variables is relatively straightforward. Although the main concern here is with inference from correspondence probability models, attention is also given to the use of the parameters of such models as a descriptive tool.

Introduction

Correspondence models extract information on the association between categorical variables. As in correspondence analysis (*see* Correspondence Analysis), correspondence models are based on a canonical parametrization of the joint distribution of the variables. Traditional correspondence analysis (Benzécri 1973, Greenacre 1984, Hill 1974, Nishisato 1980, Gifi 1990) is concerned with methods used for description and detection of patterns of association between variables via graphical displays, and does not consider the role of random sampling in the generation of the observed data from a population with an associated probability model. In contrast, correspondence models are explicitly concerned with inferential methods for the study of probability models which are fitted to observed data under the assumption that the data have been obtained by random sampling (Goodman 1985, 1986, Gilula and Haberman 1986, 1988). The parameterizations used in correspondence models may still be used to construct descriptive measures and graphs; however, unlike in traditional correspondence analysis, correspondence models involve formal statistical methods such as tests of goodness of fit and approximate confidence intervals for parameters. Development of correspondence models is most straightforward in the case in which the relationship of two categorical random variables is studied (Section Bivariate Correspondence Models). When more than two variables are involved, correspondence models may involve a division of the categorical variables into two groups (Section Two Groups of Categorical Variables). Correspondence models based on multiple correspondence analysis are much more difficult to construct (Section Multiple Correspondence Analysis).

Bivariate Correspondence Models

Let X and Y be two categorical random variables with respective ranges consisting of I and J categories indexed from 1 to I, and from 1 to J, respectively. The joint probability distribution of X and Y may be characterized by the I by J matrix p^{XY} of joint probabilities $p_{ij}^{XY} = p(X = i, Y = j), \quad 1 \le i \le I, \quad 1 \le j \le J$. The marginal probability distributions of X and Y may be characterized by the marginal probabilities $p_i^x = P(X = i), 1 \le i \le I$, and $p_j^y = P(Y = j), \quad 1 \le j \le J$. For simplicity, assume that $p_i^x > 0$ for $1 \le i \le I$, and $p_j^y > 0$ for $1 \le j \le J$. The entire family of correspondence models for bivariate distributions is based on the canonical decomposition (Hirschfeld 1935, Fisher 1940)

$$p_{ij}^{XY} = p_i^X p_j^Y \left(1 + \sum_{m=1}^{M} \rho_{im}\mu_{im}\nu_{jm}\right) \qquad [1]$$

where $M = \min(I-1, J-1), \quad 1 \ge \rho_1 \ge \rho_2 \ldots \ge \rho_M \ge 0$

$$\sum_{i=1}^{I} p_i^X \mu_{im} = \sum_{j=1}^{J} p_j^Y \nu_{im} = 0, \quad 1 \le m \le M \qquad [2]$$

and

$$\sum_{i=1}^{I} p_i^X \mu_{im}\mu_{im'} = \sum_{j=1}^{J} p_j^Y \nu_{im'} = \begin{cases} 1, & 1 \le m = m' \le M \\ 0, & 1 \le m \le m' \le M \end{cases} \qquad [3]$$

In (1), (2), and (3), for each integer m from 1 to M, the parameter ρ_m is the mth canonical correlation, the score μ_{im} is the mth canonical score of category i of variable X, $1 \le i \le I$, and the score ν_{jm} is the mth canonical score of category j of variable Y. Let the mth canonical variable μ_{Xm} associated with X be the random variable with value μ_{im} for $X = i$, and let the mth canonical variable μ_{Ym} associated with Y denote the random variable with value ν_{jm} for $Y = j$. Then μ_{Xm} and ν_{Ym} both have mean 0 and variance 1, and ρ_m is the correlation of the canonical variables μ_{Xm} and ν_{Ym}. In addition, if $1 \le m < m' \le M$, then the canonical variables μ_{Xm} and $\mu_{Xm'}$ of X are uncorrelated, and the canonical variables ν_{Ym} and $\nu_{Ym'}$ of Y are uncorrelated.

For some M^* between 1 and M, graphical display of category i of X may be based on the observed scores μ_{im} for $1 \leq m \leq M^*$ and graphical display of category j of Y may be based on the observed scores ν_{jm} for $1 \leq m \leq M^*$. An alternative approach uses graphical displays for row category i based on the correspondence scores $\rho_m \mu_{im}$ for $1 \leq m \leq M^*$ and graphical displays for column category j based on the correspondence scores $\rho_m \nu_{jm}$ for $1 \leq m \leq M^*$.

Formal inference for canonical models has generally been based on maximum likelihood. Computation of maximum-likelihood estimates has been attempted by use of a cyclic algorithm (Goodman, 1985) and by use of a scoring algorithm for parameters subject to constraints (Gilula and Haberman, 1986). Goodness of fit has typically been examined by use of likelihood-ratio and Pearson chi-square statistics. In typical cases, a chi-square approximation can be applied when the model is true. If the model only assumes that $\rho_m = 0$ for $m > M^*$, then the chi-square approximations have $(I\text{-}M^*\text{-}1)(J\text{-}M^*\text{-}1)$ degrees of freedom.

As a statistical model, (1) is a *saturated* model, for no restrictions are imposed on the joint probabilities p_{ij}^{XY}. Goodman (1985, 1986) and Gilula and Haberman (1986) consider models in which the canonical correlations ρ_m are assumed 0 for $m > M^*$ for some M^* between 0 and M. The case of $M^* = 0$ leads to the conventional model of independence of the variables X and Y. The case of $M^* = M$ is the saturated model in which no restrictions are imposed. The most common nontrivial case has $M^* = 1$. Models are also considered in which linear restrictions are imposed on the scores μ_{im} and ν_{jm} for $m \leq M^*$.

As an example, consider the data in Table 1 (Guttman 1971) on the origin of Israeli adults versus their principal worry. Several cells in the table have small values, so some care must be exercised in interpretation of customary large-sample approximation. Nonetheless, it is worth noting that the model with a single nonzero canonical correlation ($\rho_m = 0$ for $m > 1$) yields a likelihood-ratio chi-square of 29.35 on 18 degrees of freedom, so that the fit is relatively poor. On the other hand, the model with two nonzero canonical correlations ($\rho_m = 0$ for $m > 2$) yields a likelihood-ratio chi-square of only 6.49 on 10 degrees of freedom, so that the fit is quite satisfactory. The estimated canonical correlations are 0.245 and 0.124. These results suggest a modest relationship between the variables under study. The maximum-likelihood estimates of the canonical scores are provided in Table 2. Figure 1 provides correspondence scores for the column variable, and Figure 2 provides correspondence scores for the row variable. Results suggest a contrast between personal worries and other concerns, especially political ones, with subjects of Asian or African background more likely to express personal worries than subjects of European or American background. The second dimension of background appears to involve a contrast between subjects born in Israel with fathers of European or American background and other subjects. Subjects born in

Two Groups of Categorical Variables

Extension of correspondence models to apply to more than two categorical variables is a nontrivial matter. The simplest approach is appropriate if the variables can be divided into two groups (Gilula and Haberman, 1988). In this case, each group of variables can be regarded as a categorical variable with many categories, and correspondence analysis methods for the bivariate case can be applied. For example, in addition to the categorical random variables X and Y of Section Bivariate Correspondence Models let an additional categorical random variable Z be defined with values from 1 to $K \geq 2$. As an example, Gilula and Haberman (1988) consider an example with X equal to education level, Y equal to religion, and Z equal to attitude toward legal nontherapeutic abortions. Each variable in this example involves a classification into three categories, so that I, J, and K are 3. In general, let p_{ijk}^{XYZ} be the joint probability that $X = i$, $Y = j$, and $Z = k$. Then

$$p_{ijk}^{XYZ} = p_{ij}^{XY} p_k^Z \left(1 + \sum_{m=1}^{M} \rho'_m \mu'_{ijm} \nu'_{km}\right), \qquad [4]$$

where M is the minimum of IJ-1 and K-1, the ρ'_m are nonnegative and nonincreasing in m,

$$\sum_{i=1}^{I} \sum_{j=1}^{J} p_{ij}^{XY} \mu'_{ijm} = \sum_{k=1}^{K} p_k^Z \nu'_{km} = 0, \quad 1 \leq m \leq M, \qquad [5]$$

and

$$\sum_{i=1}^{I} \sum_{j=1}^{J} p_{ij}^{XY} \mu'_{ijm} \mu'_{ijm} = \sum_{k=1}^{K} p_k^Z \nu'_{km'} = \begin{cases} 1, & 1 \leq m = m' \leq M, \\ 0, & 1 \leq m < m' \leq M. \end{cases} \qquad [6]$$

Various restrictions may be imposed on the canonical parameters. For example, if Y and Z are conditionally independent given X, then $\rho_m = 0$ for any $m > (-1)$ and μ'_{ijm} depends only on i for $\rho_m > 0$. For other examples, see Gilula and Haberman (1988).

Multiple Correspondence Analysis

Multiple correspondence analysis, another approach to extension of correspondence analysis to the study of two or more categorical variables, appears in Guttman (1941). Multiple correspondence analysis can be regarded as a special case of correspondence analysis. For illustrative purposes, the case of two and three variables will be considered.

Consider the case of two categorical random variables X and Y defined as in Section Bivariate Correspondence Models. In a multiple correspondence analysis of X and Y, a canonical analysis is used to predict the joint variable (X, Y) from either X or Y, where X or Y is chosen at random. Formally, (X, Y) is predicted by the pair (U, V), where V is a random variable independent of X and Y such that V assumes the values 1 and 2 with equal probability. The variable U is X if V is 1, and U is Y if V is 2. when $V = 1$, then $U = X$, so that prediction of (X, Y) reduces to prediction of Y by X. When $V = 2$, then $U = Y$, so that prediction of (X, Y) reduces to prediction of X by Y. The canonical analysis in this case is closely related to conventional canonical analysis of the variables X and Y.

For multiple correspondence analysis of the three categorical variables X, Y, and Z of Section Two Groups of Categorical Variables the joint variable (X, Y, Z) is predicted by random choice of a marginal variable X, Y, or Z. In this case, let V be a random variable independent of X, Y, and Z which assumes value k with probability $^1/_3$ for $1 \leq k \leq 3$. Let U be the random variable which is X for $V = 1$, Y for $V = 2$, and Z for $V = 3$. Multiple correspondence analysis considers correspondence analysis of (X, Y, Z) and U. If $V = 1$, then $U = X$ and prediction of (X, Y, Z) reduces to prediction of (Y, Z) by X. If $V = 2$, then $U = Y$ and prediction of (X, Y, Z) reduces to prediction of (X, Z) by Y. If $V = 3$, then $U = Z$ and prediction of (X, Y, Z) reduces to prediction of (X, Y) by Z. The analysis differs from that in Section Two Groups of Categorical Variables in that it is symmetrical in the three variables. Thus in the example of Gilula and Haberman (1988), the analysis looks at educational level, religion, and abortion attitude symmetrically. This approach may or may not be appropriate, depending on the context. For instance, one may reasonably argue that abortion attitude reflects educational and religious background, but neither educational background nor religious background is appreciably affected by abortion attitude.

Conclusion

Correspondence models compete in practice with a number of other statistical methods in common use. In their development of canonical models, both Goodman (1985) and Gilula and Haberman (1986) compare canonical models with association models in the case of two variables. Here association models involve a loglinear parameterization similar to the parameterization used in correspondence models. Interpretations involve loglinear interactions rather than the correlations used in correspondence models, but it remains the case that scores are attached to variable categories. As noted in both papers, association models in which scores are fixed rather than estimated are special cases of conventional log-linear models (*see* Multivariate Analysis: Discrete Variables (Loglinear Models)). Goodman (1985) also discusses the relationship of parameters in canonical models to parameters in correspondence models. Gilula and Haberman (1986) and van der Heijden, Gilula and van der Ark (1999) consider the relationship of canonical models to latent-class models (*see* Factor Analysis and Latent Variable Models in Personality Psychology). In the case in which more than two variables are analyzed by division of the variables into two groups, Gilula and Haberman (1988) compare canonical models to association models in cases in which more than two variables are present.

The canonical correlations used in bivariate correspondence analysis may be used to derive formal tests of independence that compete with conventional chi-square statistics and may

be employed to ascertain the nature of departures from independence. For details, see Haberman (1981).

A variety of alternative interpretations of multiple correspondence analysis are available. For example, see Tenenhaus and Young (1985) and Gifi (1990).

Multivariate Analysis: Discrete Variables (Loglinear Models)

Shelby J Haberman, Educational Testing Service, Princeton, NJ, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Loglinear models are commonly used to analyze relationships involving discrete variables. They include models for independence and conditional independence of polytomous variables, logit models for prediction of binary variables, multinomial response models for prediction of multinomial variables, and Poisson regression models. On the other hand, loglinear models are special cases of exponential families. A unified treatment of loglinear models may be achieved by description of data concerning discrete variables in terms of tables of frequencies. In a loglinear model, each frequency is a random variable with a finite and positive expectation, and the logarithms of the expectations of the frequencies are assumed to satisfy a linear model. The frequencies are assumed to be either independent Poisson random variables or one or more independent multinomial random variables. In loglinear models, exact tests and confidence intervals are available, although such procedures are often difficult to apply. Large-sample approaches based on maximum likelihood are commonly used, and analyses based on weighted regression analysis are encountered in many important special cases. Bayesian methods of analysis have also been proposed.

Introduction

Loglinear models are a class of probability models commonly used to analyze relationships involving discrete variables. They include models for independence and conditional independence of polytomous variables, logit models for prediction of binary variables, multinomial response models for prediction of multinomial variables, and Poisson regression models. They are used both in contingency tables in which all variables under study are categorical, and in cases in which responses are categorical variables but some predicting variables may be continuous. Although numerous probability models in the statistical literature prior to 1969 are examples of loglinear models, an explicit description of a probability model as a loglinear model is not readily found in statistical journals or published books prior to Bishop (1969) and Bishop and Fienberg (1969).

The cell frequencies are random variables with positive and finite expected values, and the logarithms of the expected values of the cell frequencies satisfy a linear model. The frequencies may be independent Poisson random variables (Poisson sampling) or they may have a joint multinomial distribution with known sample size (multinomial sampling). In the case of multinomial sampling, to each cell in the table of frequencies corresponds a cell probability. The linear model for the logarithms of the expected values of the cell frequencies is defined in such a manner that the logarithms of the cell probabilities satisfy the same linear model. In a more complex case (product multinomial sampling), the table of frequencies consists of independently distributed subtables, with each subtable having an independent multinomial distribution with known sample size. Again, each cell in the table of frequencies corresponds to a cell probability for a multinomial distribution, and the linear model is defined so that the logarithms of the cell probabilities satisfy the same linear model as do the logarithms of the expected values of the cell frequencies.

Examples

Several examples of loglinear models provide an indication of their scope.

Example 1. The additive loglinear model for a two-way contingency table. As in Bishop and Fienberg (1969), consider a contingency table with frequencies n_{ij}, $1 \le i \le I$, and $1 \le j \le J$, where there are $i \ge 2$ rows and $j \ge 2$ columns in the table. Let each frequency n_{ij} be a random variable with expectation $m_{ij} > 0$. In an additive loglinear model, it is assumed that the logarithms $\mu_{ij} = \log m_{ij}$ satisfy the additive model

$$\mu_{ij} = \lambda + \lambda_i^A + \lambda_j^B \qquad [1]$$

for $1 \le i \le I$ and $1 \le j \le J$, where λ, λ_i^A, and λ_j^B are unknown parameters such that

$$\sum_{i=1}^{I} \lambda_i^A = \sum_{j=1}^{J} \lambda_i^B = 0 \qquad [2]$$

The constraints in [2] are imposed to identify the parameters λ, λ_i^A, and λ_j^B. The parameter λ is the average of μ_{ij} for $1 \le i \le I$ and $1 \le j \le J$. If $\mu_{i.}$ is the average of μ_{ij} for $1 \le j \le J$ and $\mu_{.j}$ is the average of μ_{ij} for $1 \le i \le I$, then $\lambda_i^A = \mu_{i.} - \lambda$ and $\lambda_j^B = \mu_{.j} - \lambda$. Interpretation of this model depends on the sampling assumptions concerning the frequencies. In the multinomial case, the n_{ij} have a joint multinomial distribution with known sample size $N > 0$ and unknown probabilities $p_{ij} > 0$. Thus, $m_{ij} = N\, p_{ij}$, $\log m_{ij} = \log N + \log p_{ij}$, and

$$\log p_{ij} = \kappa + \lambda_i^A + \lambda_j^B \qquad [3]$$

where $\kappa = \lambda - \log N$. Thus, the logarithms $\log m_{ij}$ of the cell frequencies satisfy the same additive loglinear model as the logarithms $\log p_{ij}$ of the cell probabilities. The probabilities p_{ij} define the joint probability distribution of a row variable A and a column variable B such that $1 \le i \le I$ and $1 \le j \le J$ and p_{ij} is the probability that $A = i$ and $B = j$. The additive model is then equivalent to the model that A and B are independent, so that

$p_{ij} = p_i^A p_j^B$, where p_i^A is the marginal probability that $A = i$ and p_j^B is the marginal probability that $B = j$. If μ^A is the average of the logarithms $\log p_i^A$ for $1 \le i \le I$, then λ_i^A is the difference between $\log p_i^A$ and μ^A. If μ^B is the average of the logarithms $\log p_j^B$ for $1 \le j \le J$, then λ_j^B is the difference between $\log p_j^B$ and μ^B.

In the row-multinomial case, the I rows n_{ij}, $1 \le j \le J$, are mutually independent for $1 \le i \le I$, and the ith row has a multinomial distribution with known sample size $N_i^A > 0$ and probabilities $p_{j\cdot i}^{B\cdot A} > 0$. The mean $m_{ij} = N_i^A p_{j\cdot i}^{B\cdot A}$, so that

$$\log p_{j\cdot i}^{B\cdot A} = \kappa + \kappa_i^A + \lambda_j^B \qquad [4]$$

where

$$\kappa = \lambda - \eta, \quad \eta = I^{-1}\sum_{i=1}^{I} \log N_i^A \qquad [5]$$

and

$$\kappa_i^A = \lambda_i^A - \log N_i^A + \eta \qquad [6]$$

Once again, the logarithms $\log p_{j\cdot i}^{B\cdot A}$ of the probabilities satisfy the same additive linear model as the logarithms $\log m_{ij}$ of the expected values of the cell frequencies. The additive model is equivalent to the homogeneity model that, for any fixed column j, $p_{j\cdot i}^{B\cdot A}$ is a constant p_j^B for each column j. The parameter λ_j^B is defined from p_j^B as in the multinomial case.

In the column-multinomial case, J columns n_{ij}, $1 \le i \le I$, are mutually independent for $1 \le i \le I$, and the jth column has a multinomial distribution with sample size $N_j^B > 0$ and probabilities $p_{i\cdot j}^{A\cdot B} > 0$. The mean $m_{ij} = N_j^B p_{i\cdot j}^{A\cdot B}$, so that

$$\log p_{i\cdot j}^{A\cdot B} = \kappa + \lambda_i^A + \kappa_j^B \qquad [7]$$

where

$$\kappa = \lambda - \eta, \quad \eta = J^{-1}\sum_{j=1}^{J} \log N_j^B \qquad [8]$$

and

$$\kappa_j^B = \lambda_j^B - \log N_j^B + \eta \qquad [9]$$

The additive model is equivalent to the homogeneity model that, for any fixed row i, $p_{i\cdot j}^{A\cdot B}$ is a constant p_i^A for each column j. The parameter λ_i^A is defined from p_i^A as in the multinomial case.

Rasch (1960) considers an additive loglinear model for a contingency table in which each frequency n_{ij} has an independent Poisson distribution with mean m_{ij}. This model is applied to analysis of a reading test in which I subjects read J passages, and n_{ij} is the number of errors made by subject i while reading passage j. The parameter λ_i^A provides a measure of relative subject ability, and λ_i^B measures relative item difficulty. This model is a special case of a general class of models encountered in the study of item responses. For further discussion of the relationship of item-response models and loglinear models, see Kelderman (1984).

The additive loglinear model leads to the quasi-independence model of Goodman (1968) and Bishop and Fienberg (1969) when [1] is only required to hold for pairs (i, j) in a subset K of the pairs (i, j) such that i and j are integers, $1 \le i \le I$, and $1 \le j \le J$.

Example 2. Logit models. As in Bishop (1969) and Haberman (1974: Chapter 8), a logit model may be described by a frequency table with elements n_{ij}, $1 \le i \le 2$, and $1 \le j \le J$. Covariates X_{jk}, $1 \le k \le K$, correspond to each column j. Each column n_{ij}, $1 \le i \le 2$, has an independent multinomial distribution with known sample size N_j^B and unknown positive probabilities $p_{i\cdot j}^{A\cdot B}$, so that $m_{ij} = N_j^B p_{i\cdot j}^{A\cdot B}$ is the expectation of n_{ij}. If $\mu_{ij} = \log m_{ij}$, then the logit $\log(p_{1\cdot j}^{A\cdot B}/p_{2\cdot j}^{A\cdot B})$ corresponding to the conditional probability $p_{1\cdot j}^{A\cdot B}$ is equal to

$$\log\left(m_{1j}/m_{2j}\right) = \log m_{1j} - \log m_{2j} = \mu_{1j} - \mu_{2j}$$

It is assumed that the logits $\log(p_{1\cdot j}^{A\cdot B}/p_{2\cdot j}^{A\cdot B})$ satisfy the linear model

$$\begin{aligned}\mu_{1j} - \mu_{2j} &= \log p_{1\cdot j}^{A\cdot B} - \log p_{2\cdot j}^{A\cdot B} = \log\left(p_{1\cdot j}^{A\cdot B}\Big/p_{2\cdot j}^{A\cdot B}\right)\\ &= \eta + \sum_{k=1}^{K}\beta_k X_{jk}\end{aligned} \qquad [10]$$

for some unknown parameters η and β_k. Thus the logarithms $\log p_{i\cdot j}^{A\cdot B}$ satisfy the same linear model as do the logarithms $\log m_{ij}$ of the expected cell frequencies. Equivalently, if δ is a Kronecker function, then

$$\mu_{ij} = \alpha_j + \eta\delta_{i1} + \sum_{k=1}^{K}\beta_k X_{jk}\delta_{i1} \qquad [11]$$

for unknown parameters α, η, and β_k. Thus,

$$\log p_{i\cdot j}^{A\cdot B} = \gamma_j + \eta\delta_{i1} + \sum_{k=1}^{K}\beta_k X_{jk}\delta_{i1} \qquad [12]$$

where

$$\gamma_j = \alpha_j - \log N_j^B \qquad [13]$$

Example 3. Interactions in a three-way table. As in Birch (1963), consider a three-way table of frequencies n_{ijk}, $1 \le i \le I$, $1 \le j \le J$, $1 \le k \le K$, with respective positive expectations m_{ijk}. Assume that I, J, and K are at least 2. The logarithm $\mu_{ijk} = \log m_{ijk}$ can always be written as

$$\mu_{ijk} = \lambda + \lambda_i^A + \lambda_j^B + \lambda_k^C + \lambda_{ij}^{AB} + \lambda_{ik}^{AC} + \lambda_{jk}^{BC} + \lambda_{ijk}^{ABC} \qquad [14]$$

where the unknown parameters λ, λ_i^A, λ_j^B, λ_k^C, λ_{ij}^{AB}, λ_{ik}^{AC}, λ_{jk}^{BC}, and λ_{ijk}^{ABC} satisfy the constraints

$$\begin{aligned}\sum_{i=1}^{I}\lambda_i^A &= \sum_{j=1}^{J}\lambda_j^B = \sum_{k=1}^{K}\lambda_k^C = \sum_{i=1}^{I}\lambda_{ij}^{AB} = \sum_{j=1}^{J}\lambda_{ij}^{AB} = \sum_{i=1}^{I}\lambda_{ik}^{AC}\\ &= \sum_{k=1}^{K}\lambda_{ik}^{AC} = \sum_{j=1}^{J}\lambda_{jk}^{BC} = \sum_{k=1}^{K}\lambda_{jk}^{BC} = \sum_{i=1}^{I}\lambda_{ijk}^{ABC}\\ &= \sum_{i=1}^{j}\lambda_{ijk}^{ABC} = \sum_{k=1}^{k}\lambda_{ijk}^{ABC} = 0\end{aligned} \qquad [15]$$

The constraints of [15] are used to identify the model parameters. For example, λ is the average of all the μ_{ijk}. As in the analysis of variance, the parameters λ_i^A, λ_j^B, and λ_k^C may be

termed main effects, the parameters λ_{ij}^{AB}, λ_{ik}^{AC}, and λ_{jk}^{BC} may be termed two-factor interactions, and λ_{ijk}^{ABC} is a three-factor interaction. In the simplest case, the table is a cross-classification obtained from a random sample of size $N \geq 1$ in which the categorical random variables A, B, and C are observed. Here A has values from 1 to I; B has values from 1 to J; and C has values from 1 to K. The count n_{ijk} is the number of observations with $A = i$, $B = j$, and $C = k$. The probability that $A = i$, $B = j$, and $C = k$ is p_{ijk}, so that $m_{ijk} = N\, p_{ijk}$ and

$$\log p_{ijk} = \kappa + \lambda_i^A + \lambda_j^B + \lambda_k^C + \lambda_{ij}^{AB} + \lambda_{ik}^{AC} + \lambda_{jk}^{BC} + \lambda_{ijk}^{ABC}$$

where $\kappa = \lambda - \log N$. If all two-factor and three-factor interaction parameters are zero, so that the logarithms μ_{ijk} satisfy the additive model

$$\mu_{ijk} = \lambda + \lambda_i^A + \lambda_j^B + \lambda_k^C$$

then A, B, and C are mutually independent. Note that the logarithms $\log p_{ijk}$ also satisfy the additive model

$$\log p_{ijk} = \kappa + \lambda_i^A + \lambda_j^B + \lambda_k^C$$

If p_i^A is the marginal probability that $A = i$ and μ^A is the average of the $\log p_i^A$ for $1 \leq i \leq I$, then $\lambda_i^A = \log p_i^A - \mu^A$.

If λ_{ik}^{AC}, λ_{jk}^{BC}, and λ_{ijk}^{ABC} are zero, so that

$$\mu_{ijk} = \lambda + \lambda_i^A + \lambda_j^B + \lambda_k^C + \lambda_{ij}^{AB}$$

then C is independent of the joint variable (A, B). If p_{ij}^{AB} is the joint probability that $A = i$ and $B = j$, then the parameter λ_{ij}^{AB} is a linear function of $\log p_{ij}^{AB}$. If λ_{jk}^{BC} and λ_{ijk}^{ABC} are zero, so that

$$\mu_{ijk} = \lambda + \lambda_i^A + \lambda_j^B + \lambda_k^C + \lambda_{ij}^{AB} + \lambda_{ik}^{AC}$$

then B and C are conditionally independent given A. In a model of no-three-factor interaction, it is assumed that the three-factor interaction terms λ_{ijk}^{ABC} are all 0, so that

$$\mu_{ijk} = \lambda + \lambda_i^A + \lambda_j^B + \lambda_k^C + \lambda_{ij}^{AB} + \lambda_{ik}^{AC} + \lambda_{jk}^{BC} \qquad [16]$$

Models of interactions in three-way tables can be applied with other sampling schemes. For example, in the Poisson case, each frequency n_{ijk} has an independent Poisson distribution with mean $m_{ijk} > 0$.

Prior to Birch (1963), the model of no-three-factor interaction can be encountered with somewhat different parameterizations. The models for interactions considered here are examples of hierarchical loglinear models. In these models, the restriction is imposed that higher order interactions are only included in models if corresponding lower order interactions are also included. Thus, if λ_{ijk}^{ABC} is in the model, then all other interactions are included. If λ_{ij}^{AB} is included, then λ, λ_i^A, and λ_j^B must also be included. This family of models is developed in Birch (1963). The models, which are analogous to linear models encountered in the analysis of factorial experiments, have been extensively used in the analysis of multivariate categorical data. Generalizations to contingency tables involving more than three variables are quite common. For example, see Goodman (1970, 1971a, b), Haberman (1974: Chapters 5 and 7, 1978, 1979), and Bishop et al. (1975). Generalizations analogous to quasi-independence models are also readily found. For example, see Haberman (1974: Chapter 7, 1979: Chapter 7).

Maximum Likelihood

The method of maximum likelihood is commonly used for estimation of parameters in a loglinear model. As shown in Haberman (1973b), maximum-likelihood estimates of the expected values of the cell frequencies are uniquely defined if they exist, and they exist if all the observed cell frequencies are positive. The same maximum likelihood estimates apply whether Poisson sampling, multinomial sampling, or product multinomial sampling is used. Maximum-likelihood estimates of expected cell frequencies can also exist if some observed cell frequencies are zero. Haberman (1973b) provides a necessary and sufficient condition for existence of these maximum-likelihood estimates. These conditions do not depend on the particular sampling method employed. In addition, if maximum-likelihood estimates of expected values of cell means do exist, then the estimates do not depend on the sampling method. Thus, the same results are obtained for Poisson sampling as are obtained for multinomial sampling.

Three basic methods are available for computation of maximum-likelihood estimates. The simplest method, if available, involves use of closed-form expressions for the maximum-likelihood estimates. This approach is available in Example 1. The estimates $\widehat{m}_{ij}$ are defined if the row marginal totals $n_i^A = \sum_i n_{ij}$ and the column marginal totals $n_j^B = \sum_j n_{ij}$ are all positive. In this case, the overall total $N = \sum_i \sum_j n_{ij}$ is positive, and $\widehat{m}_{ij} = n_i^A n_j^B / N$. Closed-form maximum likelihood estimates may be obtained for a large class of loglinear models that are commonly termed decomposable models. See Bishop and Fienberg (1969), Goodman (1968, 1970, 1971a), and Haberman (1974: Chapters 5 and 7). These loglinear models normally correspond to combinations of hypotheses concerning equiprobability, conditional independence, and independence. They are closely related to graphical models (Darroch et al., 1980).

A traditional approach to calculation of maximum-likelihood estimates is based on the iterative proportional fitting procedure developed in Deming and Stephan (1940) for use with adjustment of census sample data to conform to census population totals. This approach is readily applied in Example 3. The algorithm generates a series of approximations to the maximum likelihood estimates by means of simple multiplicative adjustments. This approach was used in Goodman (1968, 1970), Bishop (1969), and Bishop and Fienberg (1969) to study hierarchical loglinear models. In typical applications involving decomposable models, convergence is achieved after one cycle of the algorithm. More generally, convergence properties of the algorithm, together with generalizations that apply to all loglinear models, are examined in Darroch and Ratcliff (1972) and Haberman (1974: Chapter 3). A disadvantage of iterative proportional fitting is that it does not help in determination of confidence intervals for parameters.

Several versions of the Newton–Raphson algorithm (Haberman, 1974, 1978, 1979) can be used to obtain maximum-likelihood estimates. The Newton–Raphson algorithm applies to all loglinear models and is currently used in the majority of computer packages that calculate maximum-likelihood estimates for loglinear models. In some instances, the computer packages for loglinear models are contained in packages for generalized linear models. The algorithm normally converges rapidly, and by-products of the calculations may be used to estimate the asymptotic covariance matrix of the model parameters. In some cases of very large contingency tables and models with very large numbers of parameters, the Newton–Raphson algorithm can converge slower than does the iterative proportional fitting algorithm; however, this issue has gradually become less significant as computers become faster and have larger memory capacity.

Large-sample properties of maximum-likelihood estimates for loglinear models have been extensively studied under a variety of conditions. For example, if all expected cell frequencies becomes large and if the model is true (Haberman, 1977), then, for each cell in the table, the ratio between the estimated expected cell frequency and the actual expected cell frequency converges in probability to 1, and a normal approximation is available for the distribution of a linear combination of maximum-likelihood estimates of logarithms of expected values of cell frequencies. This normal approximation is readily employed to construct approximate confidence intervals for linear combinations of logarithms of expected values of cell frequencies. The same normal approximation typically applies for Poisson, multinomial, or product multinomial sampling if, in the case of multinomial or product multinomial sampling, the linear combination of logarithms of expected values of cell frequencies is identical to the corresponding linear combination of logarithms of cell probabilities. Haberman (1977) also examines much more complex cases under which normal approximations can be used.

In cases in which doubts arise concerning the accuracy of the normal approximation used to construct confidence intervals, it is possible, at least in principle, to obtain exact confidence intervals for linear combinations of logarithms of expected values of cell frequencies. The basic approach required is given in Haberman (1974: Chapter 1); however, actual use of exact confidence intervals often involves substantial computational challenges as well as a number of problems concerning the precise way to define an exact confidence interval. Agresti (1992) provides an extensive review of the issues as well as numerous references.

Hypothesis Tests

In the case of loglinear models, the most common tests of goodness of fit are likelihood ratio and Pearson chi-square statistics, although other alternatives exist (Cressie and Read, 1984). For Poisson, multinomial, or product multinomial sampling, these statistics apply to the null hypothesis that the model holds and to the alternative hypothesis that the model is not valid. Central chi-square approximations for the Pearson and likelihood ratio chi-square statistics are available if all expected values of cell frequencies are large and if the model holds. If the model is not valid but all expected cell frequencies are large, then noncentral chi-square approximations may be used.

Cressie and Read (1984) propose a power divergence family of test statistics that includes both the Pearson and likelihood-ratio chi-square and maintains the basic properties of these statistics for the case of large expected cell frequencies.

Two loglinear models may be compared by use of likelihood-ratio chi-squares. Let M and M' represent two nested loglinear models, so that validity of model M implies validity of model M'. Let L^2 be the likelihood-ratio chi-square statistic for goodness of fit of M, and let L'^2 be the likelihood-ratio chi-square statistic for goodness of fit of M'. The difference $L^2 - L'^2$ provides a likelihood-ratio test for the null hypothesis that M holds and the alternative hypothesis that M' holds but M is false. If the expected counts are all large and M holds, then $L^2 - L'^2$ has an approximate central chi-square distribution. If the expected counts are large but M does not hold, then a noncentral chi-square approximation may be considered even in the case in which neither M nor M' holds. Haberman (1977) provides conditions under which these chi-square approximations can also be effective when the sample size is large but individual expected counts are small.

In cases in which the accuracy of large-sample approximations is questionable, exact tests of hypotheses are also available. Such tests are easily implemented in a number of special cases. For example, testing the additive model for a 2 by 2 contingency table or the model of no-three-factor interaction in a 2 by 2 by 2 contingency table is quite straightforward. In other typical cases, the computational labor involved is considerable. Agresti (1992) provides an extensive review of the literature concerning exact tests.

Residual Analysis

Residual analysis provides a basic supplement to formal hypothesis tests. As in regression analysis, residual analysis of loglinear models permits a thorough search for discrepancies between the data and the model. As in regression analysis, residual analysis can involve the use of graphs to consider patterns of residuals and to detect residuals of unusual size. A basic development of residual analysis in loglinear models is found in Haberman (1973a). The raw residual for a cell is the difference between the observed and estimated expected cell frequency. The variability of the raw residual is dependent on the expected cell count, so that it is common to try to rescale the raw residual. For Poisson, multinomial, or product multinomial sampling, a simple rescaling is provided by the standardized residual. The standardized residual for a cell is the ratio of the raw residual and the square root of the estimated expected cell frequency. The sum of the squares of the standardized residuals yields the Pearson chi-square statistic. If the model holds and if the expected cell frequencies are large, then the standardized residuals have approximate normal distributions with means of 0 and variances no greater than 1. The adjusted residual is the ratio of the raw residual and the estimated standard deviation of the raw residual. If

the model holds and if the expected cell frequencies are large, then the adjusted residuals have approximate standard normal distributions.

Alternative definitions of residuals are also available. The Freeman-Tukey residuals (Bishop et al., 1975: pp. 136–141) for a cell with observed count n and estimated expected count $\widehat{m}$ satisfy

$$z = \sqrt{n} + \sqrt{n+1} - \sqrt{4\widehat{m}+1}$$

The Poisson deviance residual D for this cell satisfies the conditions that

$$D^2 = a\left[n\log\left(n/\widehat{m}\right) - n + \widehat{m}\right]$$

and D has the same sign as the raw residual $n - \widehat{m}$. These residuals are similar to the standardized residual. The sum of squares of the Poisson deviance residuals is equal to the likelihood-ratio chi-square statistic. For discussion, see Pierce and Schafer (1986). In the case of generalized residuals, a linear combination of observed cell frequencies is compared to a linear combination of estimated expected cell frequencies. Haberman (1978, 1979) provides a detailed development, references, and examples.

Model Selection

A common issue in the study of loglinear models is the selection of models. This issue is complicated in many common cases due to the very large number of loglinear models that may be considered. As a consequence, problems of multiple tests arise. Consider a case in which $c \geq 2$ loglinear models M_a are under study for $1 \leq a \leq c$, and let L_a^2 be the likelihood-ratio chi-square statistic for goodness of fit of model M_a. Approximate significance levels may be obtained for each L_a^2, and, for cases in which model M_a is nested within M_b, so that validity of model M_a implies validity of model M_b, an approximate significance level may be obtained for the log likelihood ratio statistic $D_{ab} = L_a^2 - L_b^2$ for comparison of models M_a and M_b. Based on these results, various strategies can be devised to select models (Bishop et al., 1975: Chapter 4, Goodman, 1971b, 1973; Haberman, 1978: Chapter 3). Measures of quality of fit have also been proposed by Goodman (1971b), Akaike (1974), Schwarz (1978), and Gilula and Haberman (1994). Measures of quality of fit may be employed to compare models that are not nested.

A significant issue in model selection commonly arises in large samples. The statistic D_{ab} may be very large, but the practical difference between models M_a and M_b may be quite small. To address this issue, Gilula and Haberman (1994) suggest use of information criteria to measure the practical difference between models. Their analysis depends on the information measure H_a, which is minus the ratio of the log likelihood for model M_a and the sample size N. They consider statistics such as $H_a - H_b = D_{ab}/(2N)$ and $1 - H_b/H_a$ to measure model improvement. As sample sizes increase, these measures converge to finite limits, whether or not either of the models is valid, and confidence intervals for measures are readily constructed. Information measures can be employed to assess the relative ability of the models to predict probabilities associated with observations. These measures may be used for comparisons of models that are not nested.

Conclusion

Loglinear models provide a very general approach to the analysis of discrete data. They have the attraction that numerous models can be constructed for complex relationships, maximum likelihood is readily applied, and tests of fit are easily applied. As a consequence, an extensive literature exists concerning loglinear models. Bishop et al. (1975) provide a basic overview of the subject with an emphasis on hierarchical loglinear models. Haberman (1974) provides a rigorous mathematical treatment of loglinear models, while Haberman (1978, 1979) examines such models in the context of research in the social sciences. Goodman (1968, 1970, 1971a, b, 1973) provides a fundamental series of papers on the use of hierarchical loglinear models. For a review of Bayesian approaches to loglinear models, see Agresti and Hitchcock (2005). For further consideration of logit models.

Abstract

This article deals with discrete multivariate analysis of categorical response variables. A categorical variable is one for which the measurement scale is a set of categories. For studies having two or more categorical variables, a contingency table displays the counts for their cross-classification of categories. Modeling approaches are vital for investigating association and interaction structure. Logistic regression is an analog of ordinary regression for binary response variables. Loglinear models, by contrast, are relevant for analyses analogous to correlation analyses, studying the association structure among a set of categorical response variables. Correspondence analysis is a related descriptive and graphical method. Multivariate analyses are relevant when there are several categorical response variables, such as in repeated measurement (e.g., longitudinal) studies. Recent advances here include models that address marginal components of a multivariate response and models that use cluster-specific random effects to describe the joint distribution. Other recent advances in discrete multivariate analysis include specialized models for ordinal responses and exact small-sample methods. Finally, the unifying concept of generalized linear models connects the primary categorical modeling procedures – logistic regression models and loglinear models – with long-established regression and analysis of variance methods for continuous response variables.

This article describes statistical methods for multivariate data sets having discrete response variables. Section Traditional Analyses of Discrete Multivariate Data summarizes some traditional ways of analyzing discrete data, such as analyses of two-way contingency tables. As in the multivariate analysis of continuous variables, modeling approaches are vital for studying association and interaction structure. Models for a categorical response variable, discussed in Section Regression Modeling of a Categorical Response, describe how the probability of a particular response outcome depends on values of predictor variables. These models, of which logistic regression is most important, are analogs for categorical responses of ordinary regression. The log-linear model, discussed in Section Loglinear Models, provides an analog of correlation analysis; it analyzes association patterns and strength of association. Section Sampling Assumptions discusses sampling assumptions for analyses for discrete data, and Section Alternative Model Types mentions other types of models for discrete data. Section New Methods for Repeated Measurement Data describes recent advances for analyzing data resulting from repeated or clustered measurement of discrete variables. Section Historical Notes provides some historical perspective.

Traditional Analyses of Discrete Multivariate Data

Most commonly, discrete variables are categorical in nature. That is, the measurement scale is a set of categories, such as (liberal, moderate, conservative) for political philosophy. In multivariate analyses with two or more categorical variables, a *contingency table* displays the counts for the cross-classification of categories. For instance, a contingency table might display counts indicating the number of subjects classified in each of the $9 = 3 \times 3$ combinations of responses on political philosophy and political party orientation (Democrat, Republican, Independent). Those combinations form the cells of the table.

Two categorical variables are *independent* if the probability of response in any particular category of one variable is identical for each category of the other variable. This is an idealized situation that is rarely true in practice, although like any statistical model it is sometimes adequate for describing reality. For instance, some surveys of American college students have shown that opinion about whether abortion should be legal is essentially independent of gender; that is, the percentage favoring legalization is about the same for male and female students.

Treating independence as a simple model for a contingency table, we can test its fit using statistics that compare the observed cell counts in the table to those expected (predicted) by that model. The most commonly used test statistics are

$$\text{Pearson statistic} = \sum \frac{(\text{observed} - \text{expected})^2}{\text{expected}}$$

$$\text{Likelihood} - \text{ratio statistic} = 2\sum \text{observed} \log\left(\frac{\text{observed}}{\text{expected}}\right) \qquad [1]$$

These both have large-sample chi-squared distributions. For r rows and c columns, the degrees of freedom (df) for the test equal $df = (r-1)(c-1)$, and the P-value is the right-tail probability above the observed test statistic value. These chi-squared statistics also can compare counts to expected values for more complex models than independence.

In conducting goodness-of-fit tests, one does not seriously entertain the possibility that the model truly holds; any model is false and provides a simple representation that only approximates reality. However, when the chi-squared statistics do not show significant lack of fit, benefits of model parsimony accrue from using the model fit, which smooths the sample cell proportions somewhat. Interpretations are simpler, and estimates of population characteristics such as the true cell proportions are likely to be better using the model-based estimates.

Multidimensional contingency tables result from cross-classifying more than two categorical variables, such as for studying the association separately at levels of control variables race, gender, or educational level. The model of *conditional independence* states that two categorical variables are independent at each level of a third; that is, ordinary independence applies in each *partial table*. Large-sample chi-squared tests of fit of this model, such as the Cochran–Mantel–Haenszel test, combine the information from the partial tables. Most are designed to be relatively powerful when the strength of the association is similar in each partial table. The model of *homogeneous association* states that the strength of association between two variables is identical at each level of a third variable. Goodness-of-fit tests of these models were originally formulated for stratified two-by-two tables, but generalizations exist for stratified *r*-by-*c* tables with ordered or unordered categories.

Goodness-of-fit tests have limited use, and in many circumstances it is more informative to estimate the strength of the associations. Goodman and Kruskal (1979) discussed a variety of summary measures. Those for ordinal variables, such as their *gamma* measure, are correlation-like indices that fall between -1 and $+1$. More attention has been focused on measures that arise as parameters in models. The odds ratio, discussed in the next section, is a parameter in logistic regression and loglinear models and is applicable for two-way or multi-way tables.

For estimating parameters in models for discrete data, the method of *maximum likelihood* estimation is the standard. The probability function for the data (e.g., Poisson, binomial), expressed as a function of the parameters after observing the data, is called the *likelihood function*. The maximum likelihood estimates are values for the parameters for which this achieves its maximum; that is, these estimates are the parameter values for which the probability of the observed data takes its maximum value. Except in a few simple cases, numerical methods are needed to find the maximum likelihood estimates and their standard errors. Software is reasonably well developed in the major statistical packages. It is often most natural to analyze discrete data using procedures for generalized linear models that permit non-normal responses, such as the Poisson and binomial. Examples include PROC GENMOD in SAS and the 'glm' function in S-Plus. For instance, for SAS see Allison (1999) and Stokes et al. (1995), for S-Plus see Venables and Ripley (1999), and for Stata see Rabe-Hesketh and Everitt (2000).

Regression Modeling of a Categorical Response

For multidimensional contingency tables and other forms of multivariate data, modeling approaches are vital for investigating association and interaction structure. *Logistic regression* is an analog of ordinary regression for binary response variables, and it has extensions for multicategory response variables. Like ordinary regression, logistic regression distinguishes between response and predictor variables. The predictor variables can be qualitative or quantitative, with qualitative ones handled by dummy variables.

Let p denote the probability of outcome in a particular response category (e.g., favoring the Democratic rather than Republican candidate for President). For the observations at particular fixed values of predictor variables, the number of responses in the two outcome categories is assumed to have the binomial distribution. With a set of predictors $x_1, x_2, \ldots, x_p$, the logistic regression model is

$$\log\left(\frac{p}{1-p}\right) = \alpha + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_p x_p \qquad [2]$$

The ratio $p/(1-p)$ is called the *odds*, and the natural logarithm of the odds is called the *logit*.

One reason for using the logit instead of p itself on the left-hand side of this equation is to constrain predicted probabilities to fall between 0 and 1. With a single predictor, for instance, the *linear probability model* $p = \alpha + \beta x$ permits p to fall below 0 or above 1 for many values of x; by contrast, the formula $\log[p/(1-p)] = \alpha + \beta x$ maps out an S-shaped function for which p increases or decreases according to whether $\beta > 0$ or $\beta < 0$ but always stays bounded between 0 and 1. For instance, for the decision to buy/rent a home, suppose the relationship between $p =$ the probability of buying and $x =$ annual family income (in ten thousands of dollars) satisfies the logistic regression model $\log[p/(1-p)] = 4.0 - 0.8x$. Figure 1 shows the plot of p for x between 0 and 10 (i.e., below \$100 000). The plot is roughly linear for p between 0.2 and 0.8.

The *probit model* is another model that has this S-shape. The function probit $(p) = \alpha + \beta x$ has a graph for p (or for $1 - p$ when $\beta < 0$) that has the shape of a normal cumulative distribution function with mean $-\alpha/\beta$ and standard deviation $1/|\beta|$. The probit model can be derived by assuming an underlying latent normal variable (e.g., Long, 1997). In practice, the probit model gives a very similar fit to the logistic regression model. To illustrate, Figure 1 also shows the plot of the equation probit $(p) = 2.35 - 0.47x$, which has the shape of a normal cumulative distribution function with mean 5.0 and standard deviation 2.1; for instance, a decrease in p of 0.68, from

Figure 1 Plot of logistic regressional model $log[p/(1-p)] = 4.0 - 0.8x$ and the probit regression model probit $(p) = 2.35 - 0.47x$.

$p = 0.84$ to $p = 0.16$, occurs between $x = 5.0 - 2.1 = 2.9$ and $x = 5.0 + 2.1 = 7.1$. Although the fits are very similar, estimates of α and β are on a different scale for probit and logistic models, and usually logistic parameter estimates are about 1.6–1.8 times the probit parameter estimates.

With multiple predictors, the coefficient β_k of x_k in the logistic regression model describes the effect of x_k, controlling for the other predictors in the model. The antilog of β_k is an odds ratio representing the multiplicative effect of a one-unit change in x_k on the odds. For instance, in a model for the probability in favoring the Democratic candidate for President, suppose $\beta_k = 0.40$ for the coefficient of $x_k =$ gender, with $x_k = 1$ for females and 0 for males. Then, controlling for the other variables in the model, for females the odds of favoring the Democratic candidate equal $e^{0.40} = 1.49$ times the odds for males; that is, the odds of favoring the Democrat are 49% higher for females than for males.

For quantitative predictors, simple interpretations that apply directly to the probability p rather than to the odds $p/(1-p)$ result from straight-line approximations to the logistic S-shaped curve for p. When p is near 0.5, $\beta_k/4$ is the approximate change in p for a one-unit change in x_k, controlling for the other predictors. To illustrate, suppose $\beta_k = -0.12$ for the coefficient of $x_k =$ annual income (in ten thousands of dollars) in the model for the probability of favoring the Democratic candidate. Then, for an increase of \$10 000 in income near where $p = 0.5$, the probability of support for the Democratic candidate decreases by about $0.12/4 = 0.03$, other variables being kept constant. To test the effect of a term in the model, the ratio of the estimate of β_k to its standard error has an approximate standard normal distribution, under the hypothesis of no effect (H_0:$\beta_k = 0$).

Using the estimated parameters from the logistic regression model, one can also estimate the probability p for given settings for the predictors, as

$$\widehat{p} = \frac{\exp\left(\widehat{\alpha} + \widehat{\beta}_1 x_1 + \widehat{\beta}_2 x_2 + \cdots + \widehat{\beta}_p x_p\right)}{1 + \exp\left(\widehat{\alpha} + \widehat{\beta}_1 x_1 + \widehat{\beta}_p x_p + \cdots + \widehat{\beta}_p x_p\right)} \qquad [3]$$

When all predictors are categorical, chi-squared tests analyze the adequacy of the model fit by comparing the observed cell counts to values expected under the model.

Generalizations of logistic regression apply to categorical response variables having more than two categories. A multicategory extension of the binomial distribution, called the *multinomial*, applies to the response counts at each setting of the predictors.

For nominal responses, the generalized model forms logits by pairing each response category with a baseline category. For an r-category response, the model has form

$$\log\left[\frac{p(Y = j)}{p(Y = r)}\right] = \alpha_j + \beta_{1j}x_1 + \beta_{2j}x_2 + \cdots + \beta_{pj}x_p \qquad j = 1, 2, \ldots, r-1$$

A separate set of parameters applies for each response category contrasted with the final one. For instance, if Y refers to preferred candidate and has categories (Democrat, Republican, Independent), the effect of gender on the choice between Democrat and Independent may differ from its effect on the choice between Republican and Independent. The choice of category for the baseline (the denominator of the logits) is arbitrary. Regardless of this choice the same inference occurs about comparisons of models with and without certain predictors and about estimated probabilities in the r response categories. For ordinal responses, the *cumulative logit model* describes the effects of predictors on the odds of response below any given level instead of above it (i.e., the model refers to an odds for the cumulative probability; see McCullagh, 1980). It has form

$$\log\left[\frac{p(Y \le j)}{p(Y > j)}\right] = \alpha_j + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_p x_p \qquad j = 1, \ldots, r-1 \qquad [4]$$

For further details about logistic regression models, *see* Multivariate Analysis: Discrete Variables (Overview); also Agresti (1996: Chapter 5), Collett (1991), Hosmer and Lemeshow (2000), and Long (1997).

Loglinear Models

Logistic regression resembles ordinary regression in distinguishing between a response variable Y and a set of predictors $\{x_k\}$. *Loglinear models*, by contrast, treat all variables symmetrically and are relevant for analyses analogous to correlation analyses, studying the association structure among a set of categorical response variables.

For multidimensional contingency tables, a variety of models are available, varying in terms of the complexity of the association structure. For three variables, models include ones for which (1) the variables are mutually independent, (2) two of the variables are associated but are jointly independent of the third, (3) two of the variables are conditionally independent, given the third variable, but may both be associated with the third, (4) each pair of variables is associated, but the association between each pair is homogeneous at each level of the third variable, and (5) each pair of variables is associated and the strength of association between each pair may vary according to the level of the third variable (Bishop et al., 1975).

Relationships describing probabilities in contingency tables are naturally multiplicative, so ordinary regression-type models occur after taking the logarithm, which is the reason for the term *loglinear*. To illustrate, in two-way contingency tables independence between row variable X and column variable Y is equivalent to the condition whereby the probability of classification $P(X = i, Y = j)$ in the cell in row i and in column j depends only on the marginal probabilities $P(X = i)$ and $P(Y = j)$,

$$P(X = i, Y = j) = P(X = i)P(Y = j) \qquad [5]$$

for all i and j. For a sample of size n, the expected count $\mu_{ij} = nP(X = i, Y = j)$ in that cell therefore satisfies

$$\begin{aligned}\log \mu_{ij} &= \log\left[nP(X = i)P(Y = j)\right] \\ &= \log(n) + \log\left[P(X = i)\right] + \log\left[P(Y = j)\right]\end{aligned} \qquad [6]$$

This has the loglinear form

$$\log \mu_{ij} = \alpha + \beta_i + \gamma_j \qquad [7]$$

for which the right-hand side resembles a simple linear model – two-way analysis of variance (ANOVA) without interaction. Alternatively this has regression form by replacing $\{\beta_i\}$ by dummy variables for the rows times parameters representing effects of classification in those rows and replacing $\{\gamma_j\}$by dummy variables for the columns times parameters representing effects of classification in those columns.

Similarly, loglinear model formulas for more complex models such as those allowing associations resemble ANOVA models except for predicting the logarithm of each cell expected frequency rather than the expected frequency itself. Dummy variables represent levels of the qualitative responses, and their interaction terms represent associations. The associations are described by odds ratios. Logistic regression models with qualitative predictors are equivalent to certain loglinear models, having identical estimates of odds ratios and identical goodness-of-fit statistics. For ordinal variables, specialized loglinear models assign ordered scores to the categories and have parameters describing trends in associations.

For further details about loglinear models, see Agresti (1996: Chapter 6), Bishop et al. (1975), and Fienberg (1980).

Sampling Assumptions

Inferential analysis of multivariate discrete data, like that of any type of data, requires assumptions about the sampling mechanism that generated the data. Often, such as in most surveys, the overall sample size is fixed and the multinomial distribution applies as the probability distribution for the counts in a contingency table. In many cases, certain marginal totals are also fixed, such as in experimental designs in which the number of subjects at each experimental condition is fixed. In addition, in regression-type models such as logistic regression, it is common to treat the counts at the combinations of levels of the predictor variables as fixed even if they are not fixed in the sampling design. In these cases, at each such combination the response is usually assumed to have a binomial distribution when the response is binary and a multinomial distribution when the response is multicategory; this replaces the usual normal response assumption for regression models for continuous responses. Other sampling possibilities, less common in practice, are that the sample size is itself random (i.e., no counts are fixed, such as in observing categorical outcome measures for all subjects who visit some clinic over a future time period) or, at the other extreme, all marginal totals are fixed; these lead to Poisson and hyper-geometric distributions.

Although some methods depend on the sampling assumption, estimates and test statistics for many analyses are identical for the common sampling designs. For instance, for two-way contingency tables, the chi-squared statistic, its degrees of freedom, and its large-sample P-value are the same when only the total sample size is fixed, when only the row totals are fixed, when only the column totals are fixed, or when both row and column totals are fixed.

Under standard sampling assumptions, traditional methods of inference for discrete data use statistics having approximate chi-squared or normal distributions for large samples. Alternative methods are available for small samples. Fisher's exact test, due to the famous statistician R. A. Fisher, is a test of independence in 2-by-2 contingency tables. Analogs of this test are available for larger tables and for testing conditional independence and homogeneous association in three-way tables (characterized in terms of homogeneity of odds ratios) as well as testing fit of more complex logit and loglinear models. small-sample confidence intervals for parameters such as proportions, difference of proportions, and odds ratios, result from inverting exact tests for various null values of parameters. Much of the current research in small-sample inference uses simulation methods to closely approximate the true sampling distributions of relevant statistics (e.g., Forster et al., 1996). StatXact (Cytel Software, 1999) is statistical software dedicated to small-sample discrete-data methods. Some of these analyses are also available in modules of software such as SAS and SPSS.

Alternative Model Types

For contingency tables relating several response variables, alternative statistical approaches to loglinear models can describe association among the variables. Foremost among these is *correspondence analysis*, a graphical way of representing associations in two-way contingency tables that has been particularly popular in France (e.g., Benzécri, 1973; see Multivariate Analysis: Discrete Variables (Correspondence Models)). The rows and columns are represented by points on a graph, the positions of which indicate associations between the two. Goodman (1986) developed a model-based version of this approach. He showed it has equivalences with *correlation models*, which determine scores for categories that maximize correlations between categorical variables. He also showed approximate connections with a set of *association models* that he helped to develop, some of which have loglinear model form but with scores or score-like parameters assigned to levels of ordinal variables. Clogg and Shihadeh (1994) surveyed such models.

Another graphical way of representing a multivariate relationship uses *graphical models* that study conditional independence structure among the variables. Roughly speaking, the graph has a set of vertices, each vertex representing a variable. An edge connecting two vertices represents a conditional association between the corresponding two variables. For instance, for four variables, the graph in **Figure 2** portrays

Figure 2 A graphical representation of four variables, with conditional independence between *X* and *Y* and between *X* and *Z*.

a model that assumes that X and Y are independent and that X and Z are independent, conditional on the remaining two variables, but permits association between W and X and between each pair of variables in the set $\{W, Y, Z\}$. The four edges in the graph, connecting W and X, W and Y, W and Z, and Y and Z, represent pairwise conditional associations. Edges do not connect X and Y or X and Z, since those pairs are conditionally independent. Many loglinear models are graphical models. For details, see Lauritzen (1996).

Logistic/probit regression models and loglinear models, together with long-established regression and ANOVA methods for normal response variables, are special cases of a broad family of *generalized linear models* (Gill, 2000). These models are characterized by a choice of distribution for the response variable (e.g., binomial, Poisson, normal), a function of the mean to be modeled (e.g., logit of the mean, log of the mean, the mean itself), and the variables that enter the linear model formula as predictors.

For binary data, the model using the logit transform of the probability p is the most popular generalized linear model. For count data, generalized linear models usually assume a Poisson response, sometimes called *Poisson regression models*. However, more variability often occurs in the counts than the Poisson distribution allows (i.e., there is said to be *over-dispersion*). The Poisson distribution forces the variance to equal the mean; according to it, for instance, at a given mean for Y the variance of the conditional distribution of Y cannot change as predictors are added to or deleted from the model. Methods of dealing with overdispersion include using discrete distributions for which the variance can exceed the mean, such as the *negative binomial*, and adding an extra error term to the model (a *random effect*) to account for unexplained variability due to factors such as unmeasured variables and measurement error.

Extensions of generalized linear models deal with more complex situations. For instance, sometimes the response is a mixture of discrete and continuous, such as when a certain proportion of the responses take value 0 but the rest can be any positive real number (e.g., responses to 'How much time do you spend on exercise each week?'). Sometimes observations are censored – we know only that the response falls above some point or below some point, such as when we count events of a certain type over time but cannot observe beyond the end of the experimental period (Andersen et al., 1993). Models can then focus on the continuous time to response of an event or the discrete counting of events. Depending on the application and the sort of censoring, the models have different names, including survival models, event-history models, and tobit models (e.g., Long, 1997).

New Methods for Repeated Measurement Data

For standard inference with the usual sampling assumptions, the methods discussed above treat separate observations in a sample as independent. In the social and behavioral sciences, multivariate data often results from repeated measurement (e.g., longitudinal) studies. For such studies, this independence assumption is violated. More generally, data sets that consist of clusters of observations such that observations within clusters tend to be more alike than observations between clusters require specialized methods. This was an active research area in the last 15 years of the twentieth century. New methods make it possible to extend traditional repeated measures ANOVA to discrete data and to permit various correlation structures among the responses.

For clustered data, recently developed methods enable modeling binary or categorical responses with explanatory variables, for instance using the logit transform. Two approaches have received considerable attention. In one, models address marginal (separate) components of the clustered response, allowing for dependence among the observations within clusters but treating the form of that dependence as a nuisance that is not a primary object of the modeling. The other approach uses cluster-specific random effects as a mechanism for inducing the dependence.

The marginal modeling approach has the advantage of relative computational simplicity. Estimates are obtained using the methodology of *generalized estimating equations* (see Diggle et al., 1994). With this quasi-likelihood method, rather than fully specify joint distributions for the responses, one need only model how the variance depends on the mean and predict a within-cluster correlation structure. A simple version of the method exploits the fact that good estimates of regression parameters usually result even if one naively treats the component responses in a cluster as independent. Although those parameter estimates are normally adequate under the naïve independence assumption, standard errors are not. More appropriate standard errors result from an adjustment using the empirical dependence in the sample data. Although one makes a 'working guess' about the likely correlation structure, one adjusts the standard errors to reflect what actually occurs for the sample data. An exchangeable working correlation structure under which correlations for all pairs of responses in a cluster are identical is more flexible and usually more realistic than the naïve independence assumption.

With models that apply directly to the marginal distributions, the regression effects are population-averaged. For instance, a fitted probability estimate refers to *all* subjects at the given level of predictors, and the model does not attempt to study potential heterogeneity among the subjects in this probability. Alternatively, one can model subject-specific probabilities and allow such heterogeneity by incorporating subject or cluster random effects in the model. For instance, a model might contain a cluster-specific intercept term that varies among clusters according to some normal distribution. The estimated variance of that distribution describes the extent of heterogeneity. This type of model is called a *generalized linear mixed model* since it contains a mixture of fixed and random effects. Specifying this form of model also has implications about the effects in a marginal model, but the form of model may differ. For instance, with random effects in a logistic regression model, the corresponding model for marginal distributions is only approximated by a logit model and the effects have different size (Diggle et al., 1994).

An alternative approach of dealing with the cluster terms is the fixed effects one of item response models such as the *Rasch model* (see Factor Analysis and Latent Structure: IRT and Rasch Models). In some applications with a multivariate response, it is natural to assume the existence of an unmeasured *latent variable* that explains the association structure. Conditional on the value

of that latent variable, the observed variables are independent. The observed association structure then reflects association between the observed variables and that latent variable. When the latent variable consists of a few discrete classes, such as when the population is a mixture of a few types of subjects, then the resulting model is called a *latent class model*. This is an analog of factor analysis in which the observed and latent variables are categorical rather than continuous. See Heinen (1993) and Factor Analysis and Latent Variable Models in Personality Psychology.

Historical Notes

The early development of methods for discrete multivariate data took place in England. In 1900, Karl Pearson introduced his chi-squared statistic (although in 1922 R. A. Fisher showed that Pearson's *df* formula was incorrect for testing independence) and G. Udny Yule presented the odds ratio and related measures of association. Much of the early literature consisted of debates about appropriate measures of association for contingency tables. Goodman and Kruskal (1979) surveyed this literature and made significant contributions of their own.

In the 1950s and early 1960s, methods for multidimensional contingency tables received considerable attention. These articles were the genesis of substantial research on logistic regression and loglinear models between about 1965 and 1975. Much of the leading work in that decade took place at the universities of Chicago, Harvard, and North Carolina. At Chicago, Leo Goodman wrote a series of groundbreaking articles for statistics and sociology journals that popularized the methods for social science applications. Simultaneously, related research at Harvard by students of Frederick Mosteller (such as Stephen Fienberg) and William Cochran and at North Carolina by Gary Koch and several students and co-workers was highly influential in the biomedical sciences.

Perhaps the most far-reaching contribution was the introduction by British statisticians John Nelder and R.W.M. Wedderburn in 1972 of the concept of generalized linear models. This unifies the primary categorical modeling procedures – logistic regression models and loglinear models – with long-established regression and ANOVA methods for normal-response data.

Texts covering logistic regression are, from least to most advanced, Agresti and Finlay (1997: Chapter 15), Agresti (1996), Hosmer and Lemeshow (2000), Collett (1991), Long (1997), Agresti (1990). Texts covering loglinear models, from least to most advanced, are Agresti and Finlay (1997: Chapter 15), Agresti (1996), Fienberg (1980), Clogg and Shihadeh (1994), Agresti (1990), Bishop et al. (1975). Andersen (1980) and Long (1997) discuss some alternative methods for discrete data.

Abstract

This article examines the life and work of Lewis Mumford (1895–1990), placing special emphasis on his wide-ranging publications. He was the author of more than twenty books and a thousand articles and reviews on subjects, ranging from art and literature to the histories of technology and urbanism. One of America's leading humanists, Mumford defined himself as a 'generalist' who sought an integrated approach to the study and renewal of contemporary society. He is best known as a critic of architecture and urbanism, but he believed his most lasting contributions lay in the field of cultural studies. By choice, Mumford remained largely outside of the Academy, with the result that his ideas reached a broad swath of the educated public.

Introduction

Lewis Mumford was one of the seminal cultural critics to emerge from the United States during the twentieth century. Although known chiefly for his work in architecture and urbanism, he made significant contributions to art and literary criticism, biography and autobiography, the history of technology, sociology, and political science. Largely self-taught, Mumford defined himself as a 'generalist,' one who crossed disciplines and epochs in pursuit of an 'organic' equilibrium in human affairs. This search for 'eutopia' or the good place – to use the Greek spelling and meaning that he preferred – preoccupied him over the course of a writing career that spanned an astonishing six decades (Figure 1).

Life and Work

Background and Intellectual Development

Born on 19 October 1895 in Flushing, Long Island (now part of New York City), Mumford was reared in a middle class, albeit fatherless, household on the Upper West Side of Manhattan. His youth was unremarkable, save for a series of extended walks around New York City that he undertook in the company of his stepgrandfather. He was graduated from Stuyvesant High School in 1912, but ill-health forced him to withdraw from the City College of New York before completing his baccalaureate degree. Rather than languish, Mumford undertook a regimen of self-study and self-improvement under the direct influence of Sir Patrick Geddes, the Scottish biologist, sociologist, and town planner whose ideas Mumford first encountered while enrolled in a college biology course. Mumford began corresponding with Geddes in 1918, and the latter acted as an intellectual mentor and surrogate father to the young man.

Figure 1 Lewis Mumford. Courtesy of the Lewis Mumford Estate.

Geddes, a remarkable polymath who disregarded disciplinary boundaries, advanced a Spencerian view of evolutionary change in society based upon the integrated study of a given region, including its physical surroundings, the population that lived there, and the work they performed. Over the next several years, Mumford heeded Geddes's call for 'regional survey,' the collection of detailed topographical and architectural data, beginning with the New York metropolitan area and, as his health improved, continuing up and down the eastern seaboard of the United States. This activity, reminiscent of Mumford's childhood walks, helped to focus his interest in the study of architecture and city planning, while still embracing Geddes's emphasis on the social, economic, and cultural aspects of regional development.

At about the same time, Mumford discovered Ebenezer Howard's garden city, which, in its compact form and its balance between urban and rural modes of living, dovetailed almost seamlessly with Geddes's regionalism. Among the numerous other writers who influenced Mumford's development at this early stage were the popular novelist H.G. Wells, the playwright George Bernard Shaw, the Arts and Crafts polemicists John Ruskin and William Morris, and the American Transcendentalists Ralph Waldo Emerson and Henry David Thoreau. This autodidactic phase was interrupted briefly by a stateside tour of duty with the U.S. Navy near the end of World War I. By 1919, Mumford had established himself as a promising journalist and an editor for New York's *Dial* and London's *Sociological Review*. In 1922, he published his first book, *The Story of Utopias*, a wide-ranging survey of utopian literature in which many of the following overarching themes of his career are adumbrated: the investment of artistic form with social meaning; the harnessing of technology for the common good; and the restructuring of the built environment on a human scale in balance with the surrounding region. That same year he married Sophia Wittenberg (1899–1997), who was to be his lifelong intellectual confidante and amanuensis.

Mumford's subsequent career can be divided roughly into the following three chronological stages: an early stage when he concentrated on American cultural history and criticism (*c*.1923–31); a mature stage when his focus broadened to

include all of Western civilization (*c.*1932–70); and a late stage when he reexamined his life and work in a series of autobiographical collections of writings, leading to an incomplete autobiography (*c.*1971–82).

Early Career

The 1920s found Mumford in the company of architects and planners as well as writers. In 1923, he joined the Regional Planning Association of America, a group dedicated to the overlapping ideals of Geddes and Howard, with a practical focus on the improvement of housing, the development of garden cities, and the promotion of regionalism. Its members included the editor Charles Harris Whitaker, the architects Clarence Stein and Henry Wright, the naturalist Benton MacKaye, and the housing reformer Edith Elmer Wood. The Association achieved modest successes in their planned communities at Sunnyside Gardens in the New York City borough of Queens – where Mumford and his wife bought their first home – and at Radburn in suburban New Jersey. The Appalachian Trail, a 2000-mile wilderness trail conceived by MacKaye for the mountainous spine of the Eastern United States, is the Association's best known achievement. Although he was not a designer, Mumford acted effectively as the Association's secretary and publicist.

Mumford continued to earn his living as journalist, writing chiefly criticism on a vast range of subjects for such periodicals as the *Freeman*, the *Journal of the American Institute of Architects*, the *American Mercury*, *Commonweal*, and the *New Republic*. He counted several prominent writers among his friends, including Harold Stearns, Paul Rosenfeld, and Waldo Frank. Under the influence of another close friend and fellow writer, Van Wyck Brooks, Mumford published a series of short, but insightful books on American culture in an effort to recover what Brooks termed the 'usable past.' On a superficial level, *Sticks and Stones* (1924) is an unorthodox, social history of American architecture; on a deeper level, it is a condemnation of modern architectural practice. Mumford argues that, following a halcyon early colonial period when vernacular forms predominated, American architecture became lost in a dense thicket of revival styles in its rapacious drive toward territorial expansion. Consequently, he urges his contemporaries to devise a regionally based modern architecture appropriate for the regionally based modern community. *The Golden Day* (1926) examines five writers from the mid-nineteenth century – Emerson, Thoreau, Nathaniel Hawthorne, Herman Melville, and Walt Whitman – whom Mumford believed had created a specifically American literature in touch with the regional landscape and who might be emulated by his contemporaries.

Mumford's first foray into biography, *Herman Melville* (1929), was a direct outgrowth of *The Golden Day* and one of the first studies to wrestle with the author's troubled psyche. *The Brown Decades* (1931) culminated this early period, and it was Mumford's attempt to redress some critical oversights in both *Sticks and Stones* and *The Golden Day*, particularly the cursory treatment of writer Emily Dickinson, landscape architect Frederick Law Olmsted, and architects H.H. Richardson and Louis Sullivan. Furthermore, architect Frank Lloyd Wright and photographer Alfred Stieglitz are treated as transitional figures, whose creative energies bridge the period from the brown decades to the present. Although surpassed by later, more scholarly works, these four books made a significant contribution to the fledgling discipline of American Studies. Moreover, with the unifying color metaphor of its title and the elegance of its prose, *The Brown Decades* endures as a major work of American letters.

Mature Career

The mature stage of Mumford's career extended from the early 1930s to the early 1970s, with only a brief interruption around World War II. During the Depression, Mumford continued to make his living as a journalist, but he confined his output to a few selected journals and magazines. In 1931, he began an extraordinary, 30-year tenure as the architecture critic for *The New Yorker*. His column, 'The Sky Line,' was an important platform from which he mediated between the often conflicting currents of European and American modernism. Many of his architecture columns have been collected and published in *From the Ground Up* (1956), *The Highway and the City* (1963), and *Sidewalk Critic* (1998; Robert Wojtowicz, editor). Virtually unknown today is his short but influential tenure as the magazine's art critic (1932–37). From cubism to surrealism, Mumford embraced most currents of modern art as they took tentative root in the museums and galleries of New York City and elsewhere, although he was less receptive to nonrepresentational experimentation. A selection of these columns have been published in *Mumford on Modern Art* (2007; Robert Wojtowicz, editor). That artists might lead a cultural renewal in post-World War II society forms the major theme of *Art and Technics* (1952), a published collection of lectures originally delivered at Columbia University.

Mumford, however, wanted to be known primarily as a writer of important books on weightier topics. Fresh from his modest success with the American 'usable past' project, he embarked on an ambitious three-part – later expanded to a four-part – series surveying Western civilization that became known as The Renewal of Life. Inspired by Geddes, the series examines medieval and postmedieval European history and culture from distinct perspectives utilizing an implicitly Christian, salvific paradigm. In Mumford's view, the Middle Ages represented an organic unity that was disrupted by the industrial revolution and its dehumanizing effects. Modern technology, coupled with rational planning and cultural renewal, he believed, could restore that lost unity in the present.

The first volume, *Technics and Civilization* (1934) examines technological developments from the turret windmills of Holland to the hydroelectric dams of the United States. He divides his survey into three periods, using terms borrowed from Geddes: the 'eotechnic,' or preindustrial phase; the 'paleotechnic,' or industrial phase; and the 'neotechnic,' or postindustrial phase. Near the conclusion Mumford focuses on what he terms 'basic communism,' a reorientation of the world economy along communitarian lines that derives more from the writings of Edward Bellamy than Karl Marx. Only through careful, human control, Mumford warns, can technology continue to improve the quality of modern life. *The Culture of Cities* (1938), the second and most widely acclaimed volume of The Renewal of Life, traces concurrent developments in urbanism. The last third of this book is devoted to Mumford's

eutopian vision for a new regionally planned order, citing such New Deal projects as the Tennessee Valley Authority and the Greenbelt Towns as examples of what was already being accomplished in the present. Following the book's publication, Mumford was recognized internationally as an authority on urbanism, his status reified by the placement of his photograph on the cover of *Time* (18 April 1938). Somewhat ironically, Mumford had earlier relocated his family from the urban surroundings of Queens to a small farmhouse in upstate New York. This success of *The Culture of Cities*, in turn, led Mumford to publish *City Development* (1945), a collection of urban-themed essays.

The last two volumes of The Renewal of Life, *The Condition of Man* (1944) and *The Conduct of Life* (1951), were met by less critical and popular success as they were, in some ways, eclipsed by the events of the World War that they bracketed. With tempered optimism, Mumford surveys the impact of politics, science, philosophy, and religion on the human personality and argues that the renewal of the individual is the necessary prelude to the renewal of society as a whole. Spread over a period of 17 years, The Renewal of Life had a less lasting impact than such contemporary multivolume studies of Western civilization as Oswald Spengler's *The Decline of the West* (2 vols, 1918–23) and Arnold J. Toynbee's *A Study of History* (12 vols, 1934–61), even though its first two volumes remain landmark studies in their respective areas. Invitations to write planning reports and to teach university courses resulted from the series, despite Mumford's lack of a baccalaureate degree. Earlier he had been a visiting professor at Dartmouth College (1929–35) and a lecturer at Columbia University (1931–35). In 1942, he was appointed visiting professor at Stanford University but left in 1944, as global events took precedence in his writing. Part-time academic roles would take on an even greater importance for Mumford after the War.

World War II transformed Mumford on a personal and professional level, while raising his political profile significantly. Early to recognize the threat of both Fascism and Nazism, he was one of the first left-leaning American intellectuals to advocate the U.S. intervention in the War, a point, which he argued forcefully and eloquently in *Men Must Act* (1939). *Faith for Living* (1940) offered a hopeful vision of a world freed from the totalitarian menace. Tragedy struck Mumford and his wife Sophia in 1944 when their only son – named, significantly, Geddes – was killed in action on the Italian front. Mumford channeled his grief into the writing of *Green Memories* (1947), a moving biography of his son that opens a fascinating window into the complexities of parenting in the middle of the twentieth century. Alarmed by the U.S. detonation of the atomic bomb and its potential for global destruction, Mumford, the interventionist, became – once the threat of totalitarianism had passed – Mumford, the pacifist. He became an ardent foe of the arms buildup of the Cold War, as advances in technology once again threatened to overwhelm human reason. *In the Name of Sanity* (1954) contains many of his essays on this topic. This same pacifism lay at the core of his vocal and written opposition to the Vietnam War during the 1960s.

Dissatisfied with the reception of The Renewal of Life, Mumford spent the next two decades revising basic assumptions and searching further into the past for clues into modern behaviors. A significant portion of this time was spent within the walls of the Academy, where he benefitted from contacts with colleagues in a myriad of disciplines. Mumford was visiting professor at North Carolina State University (1948–52), professor of city planning and Ford Professor at the University of Pennsylvania (1951–56; 1959–61), and visiting professor at the Massachusetts Institute of Technology (1957–61), among other places. He continued writing at a steady pace. *The Transformations of Man* (1956) was his attempt to condense the core message of The Renewal of Life into a single volume. His conclusion that 'One World man' – one who recognizes and synthesizes the rich traditions of all cultures around the globe – was about to emerge in the latter part of the twentieth century has proven to be both prescient and elusive. This reevaluation of past themes continued with *The City in History* (1961), Mumford's best known book. What he intended as a mere revision of *The Culture of Cities*, gradually evolved into an expansive, mostly new survey of Western urbanism, beginning with the Paleolithic cave and concluding with the sprawling twentieth-century metropolis. Missing was his earlier, eutopian vision of a new regional order; instead he forecasted the inevitable decline of cities unless technology, especially the automobile, were brought under control by designers and planners. The book, which won the National Book Award for Non-Fiction in 1962, solidified Mumford's reputation as America's senior authority on urbanism, although his presumptions regarding the efficacy of rational planning on city design were soon challenged by younger writers such as Jane Jacobs. Its success, moreover, spurred Mumford to publish *The Urban Prospect* (1968), yet another collection of his essays on urbanism.

Building on the momentum of *The City in History*, and at a stage in life when many of his contemporaries would have been content to garner praise and awards, Mumford reposited his views on the history of technology in what may be his most ambitious work, the two-volume *Myth of the Machine* (2 vols, 1967, 1970). In volume one, *Technics and Human Development* (1967), he put forward what he believed was his most original insight: that the ancient rulers of the eastern Mediterranean world exerted insidious control over human labor through the employment of massive work units or 'megamachines.' Although he argued in volume two, *The Pentagon of Power* (1970), that modern technology made such human megamachines obsolete, its all-embracing power, left unchecked by human reason, would eventually lead to global destruction. Critical and popular reaction to *The Myth of the Machine* was mixed, but Mumford's critique of the political and scientific establishment, which he identified as masterminding the modern megamachine, won him wide admiration among a younger, more reform-minded generation.

Late Career

Mumford relished his position as a public intellectual, and he spent the last two decades of his life engaged in various activities related to the stewardship of his considerable legacy. He donated his personal papers to the Van Pelt Library of the University of Pennsylvania in Philadelphia and his graphite,

ink, and watercolor sketches – many of them dating to the regional surveys of his youth – to Monmouth College, now Monmouth University, in West Long Branch, New Jersey. Several collections of his earlier writings were published: *Interpretations and Forecasts: 1922–1972* (1973); *Architecture as a Home for Man* (1975; Jeanne M. Davern, editor); and *The Lewis Mumford Reader* (1986; Donald L. Miller, editor). Two autobiographical collections – *Findings and Keepings* (1975) and *My Works and Days* (1979) – preceded the publication of his autobiography, *Sketches from Life* (1982), which covered only the first half of his long life. In addition, Mumford's correspondence with such key friends and colleagues as Van Wyck Brooks, Frederic Osborn, Patrick Geddes, and Frank Lloyd Wright, have been edited and published, providing a fuller understanding of his formidable but engaging personality. Moreover, he received numerous accolades, including the Royal Institute of British Architects' Gold Medal (1961), the Presidential Medal of Freedom (1964), and the National Medal of the Arts (1986). Mumford died quietly at his country home in Leedsville near Amenia, New York, on 26 January 1990.

Critical Assessment

Mumford's belief that society could be improved through rational and ecologically sound planning, marks him as a committed modernist. Postmodern scholars – who emphasize, among other things, the fragmentation of meaning and the failure of planning – have largely ignored him. Nevertheless, most of Mumford's books remain in print, and his name is beginning to appear with increasing frequency in both popular and scholarly contexts. Mumford's wide-ranging legacy as a generalist has been difficult for any one scholar to address; some have selected one aspect of his work, while others have joined together in delivering group assessments. Examples of the latter include the special issue of the American journal *Salmagundi* (Summer 1980) and *Lewis Mumford: Public Intellectual* (1990; Thomas P. Hughes and Agatha C. Hughes, editors), a collection of essays that focus on Mumford's lifelong involvement with technology. As its title suggests, Donald L. Miller's *Lewis Mumford: A Life* (1989) provides a comprehensive and often insightful overview of Mumford's life. Frank G. Novak Jr., focuses more narrowly on one aspect of Mumford's writing in *The Autobiographical Writings of Lewis Mumford* (1988).

In *Beloved Community* (1990), Casey Nelson Blake examines Mumford's relationship to the 'young Americans,' a group of New York intellectuals searching for cultural renewal in the aftermath of World War I. Shuxue Li's *Lewis Mumford: Critic of Culture and Civilization* (2009) discusses Mumford in the context of Karl Marx and Max Weber. Mumford's contributions to architecture and urbanism are the subject of Robert Wojtowicz's *Lewis Mumford and American Modernism* (1996), while Heinz Tschachler discusses Mumford in a German context in *Lewis Mumford's Reception in German Translation and Criticism* (1994). Mark Luccarelli focuses on Mumford's concern for regionalism and the environment in *Lewis Mumford and the Ecological Region: The Politics of Planning* (1995). Numerous dissertations, moreover, have addressed one or more aspects of Mumford's work. As yet, however, little has been written about Mumford outside of the United States, even in Great Britain, where many of his books were published in separate editions.

Museums

Jennifer Barrett, The University of Sydney, Sydney, NSW, Australia

Abstract

Museums around the world assume many different forms, yet take as their reference point the museum practice of previous centuries. This article acknowledges past practice before identifying contemporary developments in museums as these institutions respond to challenges, locally and internationally, that affect the museum form. What follows are potential directions for museology, recognizing that museums are increasingly responding to, and sometimes initiating, their changing social context.

Introduction

The museum emerged in the late eighteenth century as a public institution, linked with the 'universal project of democracy,' beginning in 1793, during the French Revolution, with the opening of the Louvre in Paris as the first public museum. Many major museums were reconstituted from private collections to become significant sites tracking material culture, as well as scientific and cultural achievements of communities, cultures, and places through the ages. They came to be *indicative* sites for the international politics of imperialism and the ensuing struggles that followed over the next two centuries. Museums, in this sense, include the building and its roles, activities, collections, engagement with its visitors, and its displays. Museums have been places with which to think about the history of ideas and their relation to society. Museums also link societies, through international networks and practices such as the exchange of ideas, objects, and controversies. Contemporary museum practice, like many academic disciplines, has responded to changes in societies around the world, and continues to do so.

The Origins of Museums

The word 'museum' is Latin from the Greek word '*mouseion*' (Alexander, 1979). The term initially meant 'the abode of the muses' which were believed to be groves on Mounts Parnassus and Helicon. Later these became temples, then universities with many colleges (Dixson, 1919: 3). Some of the earliest museums were in cities such as Alexandria, Athens, and Rome. They were associated with knowledge creation and dissemination (similar to the role of modern universities), or were devoted to displaying captured treasures. With the destruction of the city of Alexandria, the term 'museum' almost disappeared, "and was only revived with the arts and sciences about the middle of the seventeenth century" (Dixson, 1919: 3). While the art collections of royalty and wealthy buyers were the forerunners of public art galleries, and the royal menageries became the predecessors of modern zoological gardens, the museum emerged from the private 'cabinet of curiosities' to become the public collection of history, anthropology, geography, and technology. Debate about the birth of the 'public museum,' and which was the first, has wavered between The British Museum (which developed from the will of Sir Hans Sloane, who died in 1753 and left his massive private collection as the basis for the establishment of The British Museum) and the Museé de Louvre.

The fifteenth-century Medici Palace in Florence is often considered the precursor, with its select invitations to visit, its acquisition and collection practices, displays, and philanthropy. The Medici's use of its collections and its granting of access to them shifted from the private realm and signaled the way in which museums would become signifiers of knowledge and power in new ways for centuries onwards (Alexander, 1979). There are other important developments in the history of museums that are worth acknowledging: notably the first university museum, which was opened in Basel in 1671, and the Ashmolean Museum in Oxford, which was established as the first public natural history museum in 1683 (Barrett and McManus, 2007).

The Evolution of the Modern Museum

Museums in the Eighteenth Century

The 'modern museum,' from which our contemporary museums have emerged, was an important part of changing social values and practices in the nineteenth century. It was also part of the experience of modernity. Not only did the number of cultural institutions increase, but also access to museums and other cultural institutions was more widespread. Moreover, the displays were more likely to reflect the world of the new merchant classes and the everyday experience of the city, rather than the world of royalty.

Prior to the late eighteenth century, 'museums' were generally "collections of valued objects [that] formed a part of the cultural accessories of power in contexts in which it was the organisation and transmission of power within and between ruling strata rather than the display of power before the populace that was the point at issue" (Bennett, 1995: 27). The opening of the Louvre in Paris as the first public museum in 1793 was a significant departure from the curiosity cabinets inside palaces, the collections of the clergy, and the collections of the merchants, which imitated the collections of royalty (see Hooper-Greenhill, 1992). The idea of the Louvre palace being a royal art gallery was advocated much earlier by Lafont de Saint-Yenne in 1747, largely because the royal collection was in

storage and was inaccessible and a royal art gallery would be a monument to the king and the glory of France should it be opened for the display of great works of art (Duncan and Wallach, 1980).

It is important not to mistake the eighteenth-century art museum for the fully formed public, national institution of the nineteenth century. According to Nick Prior, the state was yet to play a formative role in the eighteenth century, and the nation was yet to be brought into line with the state. Furthermore "culture was yet to be subsumed under the latter's socio-political remit" (2002: 35). He adds

> …museums in the eighteenth century were not usually owned by the state on behalf of the people as a corollary to citizenship, governance and democracy. Visitors were subjects not citizens and power was represented 'before' them rather than 'for' them.
>
> Prior, 2002: 35

The change from the princely collections of the late eighteenth century to the public museum of the twentieth century was a journey replete with debate about what constitutes a museum, what role a museum should have in society, who attended museums and what benefit was gained by doing so, and how museum practice should accommodate visitors. Many of these concerns, and some of the answers, predate the 'new museology' that was packaged and presented by Peter Vergo (1989).

Emerging Modern Public Museums in the Nineteenth Century

By the middle of the nineteenth century, the emerging modern public museums were a vital part of industrialization and colonial processes. Museums cataloged and presented socio-economic and technological change to their audiences. The major imperial museums in London, Paris, and later Berlin displayed the wealth and curiosities of each country's dominions to the central cities of those empires, which often had significant environmental and cultural impact on those colonies and territories (Barrett and McManus, 2007). The majority of today's great art museums of the Anglo-Saxon world were created in the Victorian Age; this influenced cultural development in the main metropolitan centers and the development of museum culture all over the world (Barringer, 2006).

The nineteenth century saw a rapid and unprecedented growth in the number of museums. While the study of natural history is much older than the nineteenth century (see Barrett and McManus, 2007), by 1900 there were 150 museums of natural history in Germany, 250 in Britain, and 300 in France (Sheets-Pyenson, 1988). The increasing number of museums was not confined to the imperial powers: Sheets-Pyenson (1988) noted that in 1900 there were 250 natural history museums in the United States, while Thomas Storie Dixson, in 1919, observed in 1903 that there were 31 natural history museums in New York state (population 7 million) and 10 in California (population 1.5 million).

The growth in the number of museums resulted from the confluence of technological progress and ideas about civilized societies. The technological progress of the eighteenth and nineteenth centuries enabled various countries in Western Europe to explore and colonize distant lands. The display of objects from these colonies in the largest cities of the imperial powers not only showed their citizens what they possessed, but also aimed to fulfill the earlier goals of leading scientists, such as Francis Bacon, to broaden knowledge and challenge the intellect. The orderly display of objects, their perusal, and the resultant education of the viewer were intended to engender a fascination with the world, and a respect for authority, particularly from the working classes.

In addition to the large public museums in the most powerful cities, private museums existed where individuals, such as Sir John Soane, collected objects of personal interest. Many of these private museums have not survived, thereby making the Sir John Soane Museum in London a modern-day rarity, much like the Pitt Rivers Museum in Oxford, of interest partly because it is a museum of a museum.

The Educational Value of Museums in the Eighteenth and Nineteenth Centuries

Museum Buildings

The idea that museums and collections had a purpose and value other than being private collections of personal interest of their owner was the foundation for the public museum. The governments of different countries began to acquire by various means the collected treasures of individuals, and established collections that would be open for the public. The buildings that these collections were housed in were often unsuitable for the 'reception and proper display of works of art and archeology.' This influenced the ability of museums to display the objects appropriately, and "made both casual observation and careful study of most of the objects a burden instead of a pleasure" (Dana, 1917 cited in Anderson, 2004: 17).

The critique of museums as being 'gloomy' and 'dull' highlighted some of the concerns in the nineteenth century about the buildings that museum collections were housed in, and the role of the museum. John Wood (1887: 384) wrote that "full of interest to the expert, there is no concealing the fact that to the general public a museum, of whatever nature, is most intolerably dull…." He proposed to create separate museums for the education of pupils and for the higher educated people who would undertake more complex study in the museum.

Relationships with the Public

This concern about the educational levels museum also connects with debates about whom the 'public' was that public museum should be attempting to attract. Much was made of the importance of educating the working man and his family. This involved both the education and the entertainment of the working classes, often to lure them away from public houses (i.e., taverns). Various accounts of late-nineteenth-century museums highlight the challenges that some of these museums faced in being public, while observations about the use of museums by various social classes questioned the value of

claims about the civilizing and educating role of museums for 'the masses.'

In a related vein, Wood wrote of the educational value of museums. He desired to "construct a museum especially adapted to the despised Tom, Dick and Harry, which would amuse them, should be of such a nature as to compel them to take an interest in the subject, and perchance to transform them into the Thomas. H. Huxleys, Richard Owens, and P. Henry Gosses of the next generation" (Wood, 1887: 391). Although some museum curators and boards realized the importance of entertainment and education in the nineteenth century, these functions continued into the twentieth century, well before the rise of the 'new museology.'

The counter argument to this perspective, and one that is sometimes raised about the educational value of contemporary approaches to museum practice, is the writings of Stanley Jevons in the late nineteenth century. Jevons was not against the educational value of museums, but he argued that it varied significantly and should not be assumed. According to Jevons (1883: 55), the "advantage which an individual gets from the visit may vary from nil up to something extremely great," and "the degree of instruction derived is quite incapable of statistical determination." Importantly, Jevons critiqued the notion of visitor studies, which became even more popular in the twentieth century, by noting

> …There seems to be a prevalent idea that if the populace can only be got to walk about a great building filled with tall glass-cases, full of beautiful objects, especially when illuminated by the electric light, they will become civilized. At the South Kensington Art Museum they make a great point of setting up turnstiles to record the precise number of visitors, and they can tell you to a unit the exact amount of civilizing effect produced in any day, week, month, or year. But these turnstiles hardly take account of the fact that the neighbouring wealthy residents are in the habit, on a wet day, of packing their children off in a cab to the so-called Brompton Boilers, in order that they may have a good run through the galleries.
>
> Jevons, 1883: 55

While Jevons highlighted the limitations of equating educational value with the counting of visitors, it was apparent that museums were a form of entertainment as well as supposedly being educational. Concerns about entertainment values of the museums overriding educational values have continued to this day.

The growth of museums in the nineteenth and twentieth centuries can be partly attributed to the notions of educating and civilizing societies, particularly the lower classes. Museums were an integral part of the colonial project during the nineteenth century. Henare (2005: 15), writing about New Zealand in 1840, noted "…the establishment of a learned society with its ubiquitous museum was among the earliest tasks of founding a new settlement." This notion of civilization also operated in rapidly growing cities in the United States. The development of a major public museum announced that the city had 'arrived.' As art historian Carol Duncan (1995: 54) observed, "a big, showy art museum could announce to both national and international business and banking communities the arrival of a city financially and politically." The same author recognized that museums 'conferred social power' and that they reinforced class boundaries while simultaneously appearing "as unifying and even democratizing forces in a culturally diverse society" (Duncan, 1995: 54).

Education as Power

Social and cultural theorist Tony Bennett has made the sharp observation that "while late-nineteenth-century museums were thus intended *for* the people, they were certainly not *of* the people in the sense of displaying any interest in the lives, habits, and customs of either the contemporary working classes or the laboring classes of pre-industrial societies" (Bennett, 1988: 64, emphasis in original). Pierre Bourdieu and Alaine Darbel (1969, cited in Bourdieu et al., 1990) argued that museums, particularly art museums, purport to be accessible to all, but are not accessible to the working classes. According to these authors, even if there is no admission charge to enter, attendance is voluntary and working-class people do not have the cultural capital to feel comfortable in these spaces or to understand how to decode the objects. Bennett's point (1988: 64) extended to the display of objects in museums. One function of museums was to impress upon visitors the power of the state. Initially, this meant that following on from the private collections of wealthy individuals, in the cabinet of curiosities, displays were comprehensive: virtually everything collected was displayed. The criteria for collection and display of material were often uniqueness, distance between the location of the material and its display, and the individual (sometimes aesthetic) properties of the object. In the late nineteenth century, as collections expanded rapidly due to colonization, displays in many major museums became selective. Sir William Flower, Director of the Natural History Museum in London, advocated displaying fewer objects in the public exhibition so that lay visitors had space to view the objects and could gain a general understanding and appreciation of nature (Flower, 1898; Sheets-Pyenson, 1988). The full collection was available to specialist researchers to conduct scientific inquiry.

Museums, along with various organizations, such as the Royal Society in London, were responsible for promoting scientific and cultural advancement, and were influential in the promulgation of ideas about nature. Museum curators taught at universities, and museums were involved in research activity (Yanni, 1999). The modern museum was a product of the late eighteenth and nineteenth conceptions of 'the public' and of citizenship. Notes that the modern museum, as part of a new relationship between the public and the state via public cultural institutions, "cannot be adequately understood unless viewed in the light of a more general set of developments through which culture, in coming to be thought of as useful for governing, was fashioned as a vehicle for the exercise of new forms of power" (Bennett, 1995: 19).

Changes to Museums in the Twentieth Century

Changing Functions of Museums

The early part of the twentieth century saw the continuation of many trends established in the latter part of the nineteenth century. This included the development of new museums and

expanding collections of established museums. During the twentieth century museums continued to increase in numbers throughout the world, with the United States alone having an estimated 17 500 museums in 1995 (American Association of Museums, 1999). Robinson (2006) noted that most American museums have been established since 1970. Visitor numbers have also increased substantially, but perhaps more importantly than quantifying the number of museums and their visitors, it is necessary to discuss the significant changes to museums during the twentieth century.

In terms of museum collections, Theodore Low in 1942 preempted the latter debates about the role of the curator and the idea of popularizing the museum by commenting on the conservative nature of curators, who he saw as focusing on the arrangement of exhibitions without sufficient consideration of the needs of the public and how they would understand the arrangement. Low also critiqued the directors of the museums, who he said, following tradition, "have been much more interested in the building up of collections and in the scholarly prestige of the institution than in making it useful" (Low, 1942 cited in Anderson, 2004: 33).

Other authors saw a major change between the museums of the nineteenth and twentieth century. Lucas (1908 cited in Genoways and Andrei, 2008: 59) wrote about the changes in public museums in the 25 years prior to this time: "one of the great differences between the old museum and the new is that the one displayed objects while the other aims to illustrate ideas." In other words, the culture of collecting was being maintained, but in many museums the culture of display was changing. He cites the example of displaying birds. Rather than having many birds on display, which would have little meaning for the average museum visitor, the new museum would display "a single group showing one of these birds at home, the purpose of which is to show the conditions under which birds live and to interest the beholder in the study of bird life" (Lucas, 1908; cited in Genoways and Andrei, 2008: 59).

Emergence of the Universal Survey Museum

As new cities emerged, they generally developed new museums. This process accelerated later in the twentieth century, partly as a result of increased leisure time, greater awareness of the importance of history, and the ongoing desire of cities and towns to gain recognition and status. Among the museums, the presence of highly visible universal survey museums such as the Metropolitan Museum of Art in New York and the National Gallery of Art in Washington, D.C., remained particularly noteworthy and sometimes controversial.

The Universal Survey Museum, an idea derived from the Louvre and nineteenth-century thought about collecting, displaying, and the role of museums in countries that were politically and economically powerful, reached its zenith in the United States in the twentieth century. Universal Survey Museums were based on the idea that elaborate, dedicated museum buildings housed not only art but also material culture significant to history. According to Duncan and Wallach (1980: 466), the National Gallery of Art in Washington, D.C., which was completed in 1941, is "perhaps the most complete realization of the universal survey idea in America." It is a museum "which could be anywhere in the Western world" and "claims the heritage of Greco-Roman civilization as an abstract and universal value" (Duncan and Wallach, 1980: 466).

The proliferation of museums in recent times is partly linked to the demise of the universal survey museum idea. Museums in the twentieth century became more specialized, and began to focus on the needs of particular audiences and to represent cultures that were absent from the great universal survey museums.

Funding

In addition to the recognition of diverse constituencies (which could be seen as a postmodern approach to what had formerly been called 'the public'), many museums in the late twentieth century engaged with visitors of the museum as consumers and customers. This development arose in part because of the attitude of some governments toward the funding of museums, which, along with other public institutions such as libraries, were expected to be more self-sufficient and able to work within the opportunities and constraints of market forces. One response to this situation was the creation of the 'blockbuster' exhibition, for which visitors would pay and then consume the accompanying merchandise being sold in the museum shop, now expanded and easily accessible as visitors left the museum building. Emma Barker (1999: 127) noted "although large-scale, highly publicized art exhibitions drawing several thousand visitors took place as early as the mid-nineteenth century, the blockbuster show as we know it is a relatively recent phenomenon." She suggested that the main characteristics of the blockbuster exhibition are that it is shown in two or three cities, that it is almost always sponsored by the corporate world, that it has advance booking and should attract a minimum of 250 000 visitors (Barker, 1999). Barker (1999) gives Thomas Hoving, the Director of the Metropolitan Museum of Art in New York from 1967 to 1977, the credit for conceiving the blockbuster format as a way of popularizing the museum and countering claims of elitism, although Prior (2005) dates it earlier to the Fourth Plan (1962–65) and André Malraux in Charles de Gaulle's government in France. The continued existence of the blockbuster is likely due to the combined impact of potentially high financial returns and the ability of the museum to avoid charges of elitism. The blockbuster approach has its downsides, including long queues, financial risk if not well attended, possible closure of other exhibitions, and the potential siphoning of visitors away from smaller, less central museums.

New Museology

Despite, and in some cases because of, these developments in many museums, it is apparent that by the late twentieth century museum practice in places such as Australia, Canada, the USA, New Zealand, and the UK needed to respond to the different experiences of diverse communities they were trying to attract. Many of the critics were coming from outside the museum sector. One response to their critiques, and a major compilation of them, was the emergence of the 'new museology' (Vergo, 1989), which can be characterized as an approach promoting access and participation in the functions of the museum by diverse audiences so as to reflect the democratic

project of the modern museum. New museums emerging in places such as Noumea (Tjibaou Cultural Centre) and Vanuatu (Vanuatu Cultural Centre and National Museum) celebrate distinct local cultural practices (something akin to community cultural centers), and highlight existing cultural heritage while having the capacity to intersect with international museum networks on matters such as repatriation and illegal trafficking of cultural heritage. Diversity and identity politics have highlighted this approach and still tend to inform contemporary museum practices in the early twenty-first century.

Attempts to further democratize the museum – not just in terms of what was represented within museums but how they operated as democratic institutions – would change the public engagement via exhibitions, collecting, and programing. Museums have thus remained a complex and important part of the public sphere that engage not only within the boundary of local communities and nation-states but transgress these territories to engage with international museum networks.

The Contemporary Museum

Museums and Social Change

Within such a framework, the strategies used by museums seek to inspire individuals and publics to reflect deeply on their place in the world and the experience of others, whether it is about the history of imperialism, colonialism, or the resulting development of collections and their contemporary legacy for communities and nations. The complexity of these issues is acknowledged and embraced.

Recognition of the complexity of museums, and the impossibility of being able to be all things to all publics, has resulted in different forms of museology: where in the nineteenth century there was a singular museology, in the twenty-first century there are various approaches such as "appropriate museology" (Kreps, 2008), or "collaborative museology" (Schultz, 2011) and a social inclusion approach to museum practice (Sandell, 2002). The participatory museum (Simon, 2010) has also been promoted by museums that are seeing increased engagement in their virtual form with the use of crowd sourcing to connect communities across the institution and to enhance knowledge of collections and their uses within situated communities and beyond. Developments in new media in the late twentieth century soon went beyond interactivity to the notion of the dialogic museum (Witcomb, 2003). While the Web made accessible information about collections, their location, and basic information for museums and their publics, museum blogs, ways of adding information about collections by the publics and new forms of interaction with audiences have became central to many museum functions.

Human Rights

As discussed previously, museum developments since the twentieth century result not from more traditional forms of collecting and display that characterized the nineteenth century, but from using archives, both personal and state-owned, to produce new experiences of the museum. Such museums are not necessarily founded on the basis of collections, since collections may not exist due to the subject matter, but on principles of justice and democracy, the rationale that museums are effective places to commemorate and memorialize, and that they may also be sites of negotiation and contribute to restoring social justice.

An increasing number of museums and exhibitions are focusing on producing experiences for audiences that require an affective engagement (Witcomb, 2013). Rather than emphasizing their collections or a well-received representation of an event, period, or idea, these museums and their exhibition practices use strategies to produce reflective experiences with a view to inspiring deeper and more critical engagement with subject matter. To some extent, we see this with the rise of human rights museums and with memorials commemorating atrocities, such as genocide.

A number of different kinds of Human Rights museums currently in operation have changed contemporary understandings of what a museum can or should be. A group of museums dedicated to overcoming social injustices, particularly in the area of human rights, includes (according to Terence Duffy in the late 1980s) Museums of Remembrance, Holocaust and Genocide Museums, Museums of Slavery, Museums of African-American Civil Rights, Prison Museums, and Museums of Torture.

In 1999, the International Coalition Of Sites of Conscience, a network of historic sites, was founded by Ruth Abram and dedicated to remembering past infringements on justice while making explicit these infringements' contemporary legacies (see www.sitesofconscience.org). At its founding, the Coalition comprised nine sites on five continents and included in its membership the District Six Museum (South Africa), the Gulag Museum (Russia), the Liberation War Museum (Bangladesh), the Lower East Side Tenement Museum (the USA), and the Maison des Esclaves (Senegal).

Since the founding of many of these museums, a network of like-minded institutions has formed. The origins of institutional members range from those of established democracies (such as the Canadian Museum for Human Rights in Winnipeg, Manitoba) to those of fledgling democracies in postconflict societies, such as the South African Holocaust Foundation. Some institutions display Human rights and Holocaust exhibitions within a museum, e.g., The Imperial War Museum, London.

In 2010, the Federation of International Human Rights Museums (FIHRM), led by the National Museums Liverpool, was founded to build on an earlier initiative of the Coalition of the Sites of Conscience (under the auspice of the International Council of Museums). FIHRM is premised upon two key assertions: first, the roles of museums are changing; and second, museums have acknowledged a growth in their social responsibility (see www.fihrm.org). To meet such expectations, museums may recast existing collections to engage with communities, or use new technologies to link the museum or site to international networks with similar concerns. Digitization of collections and social media allows new ways to link with audiences, educational institutions, and organizations relevant to a museum's strategic goals.

The Future of Museums

The recent proliferation of museums is likely to continue into the future, despite funding constraints in many countries.

The development of new museums whose intended audiences are currently marginalized, the trend toward more commemoration of events, and the desire to attract tourists and inward investment will all contribute to an increase in the number of new museums in the developed countries. Simultaneously, many existing museums will be redeveloped, expanded, and 'rebranded' to achieve relevance (again). This is partly in response to the same forces creating new museums.

There will be more museums in countries that do not share much heritage with the existing museums in developed countries. Some of the newly rich Arabian oil states have consciously planned a development strategy beyond exploiting their finite reserves of oil, and they are using the revenue generated from the sale of this fossil fuel to develop a range of cultural industries. Museums are central to their cultural industries, which include both the establishment of new museums and the importation of branches of existing universal survey museums, such as the Louvre. Newly powerful countries such as China, and perhaps in the future India, will display their power through museums, in similar ways as European countries and the United States in the nineteenth and twentieth centuries. This is already occurring, with the creation of a massive museum complex known as M+ (Museum Plus) on reclaimed land in West Kowloon, in the Hong Kong Special Administrative Region. Earlier conceptions of this development included branches of the universal survey museums and the likelihood of an internationally recognized museum architect, before public pressure led to the plans being abandoned in favor of a locally driven process of consultation, discussion, and development.

Issues of repatriation are also likely to be foregrounded, and highly controversial. Claims for heritage and possession will broaden from a relationship between universal (and sometimes university and city-oriented) museums with indigenous people to include relationships between universal survey museums in the United Kingdom, France, Germany, and the United States of America with powerful museums, strongly supported by government, in the People's Republic of China. These museums are emerging not just in a different era, but also in different cultural contexts from the museums of so-called developed countries. The notions of 'public,' 'being public,' and 'public space' will inevitably be different in relation to these museums.

The engagement with the Internet is both a challenge and opportunity for the future of many museums. The digitization of collections and the use of social media, while appearing to be a gateway for new forms of 'audience engagement,' have revealed the limitations of the methods used in museums to understand audiences and publics. In many ways, technological developments in museums have moved faster than policy and planning. The potential of social media to usher in a new era in museum practice brings new pressures, not only in the securing and allocation of resources, but also in how museums argue that these practices enable the museum to be *more* public than their predecessors. Fundamental questions of engagement remain, such as maintaining inclusivity beyond the voices of the most frequent bloggers. Social media has caused, and will continue to stimulate, changes from the predigital era practices of museums, but it will not be a panacea for the challenges facing museums today and into the future. Nor is it immune to fundamental questions asked of museums. Embracing the complexities inherent in concepts such as the public, public space, public sphere, and community will still be required.

Rather than seeing the passing of the modernist idea of a museum, contemporary museum practice shows its power relationship changing, albeit unevenly, around the world. Museums will continue to reflect dominant systems of knowledge and power in broader society, changing as they do. There are times, as in the work on repatriation in the 1970s and 1980s, when museums were ahead of institutions of the state. As these developments were influenced and in many ways tied to social movements such as civil rights, they worked with these discourses to make change in the museum sector. Collaboration and reciprocity were central and remain so in this field. As disciplines of knowledge have evolved and developed, museums have changed.

There will always be a role for what is becoming known as 'the traditional museum' – a building displaying artifacts for the education and entertainment of visitors. Over time some of these museums will choose to adapt to new technologies and embrace the complexities that this development entails. In fact, there are few examples of museum display techniques and curatorial practices that a curator from the nineteenth century would immediately recognize. In the future museums are likely to be as diverse, if not more so, than the museums that currently exist, with one potential future being a plethora of museums, engaged with their diverse publics and with each other through traditional communications and the innovative use of digital technologies. The challenge will be how to manage the relationship with their diverse communities – virtual and on the physical site. Different modes of access for visitors will not be the only significant change. How the museum operates as a producer of knowledge for and with communities and research purposes will change further. The roles of collecting, collections, and exhibitions within these changing environments are continually being renegotiated. With this come new ethical concerns, about cultural property and its uses. As outlined above, creating reflexive experiences is emphasized.

In conclusion, many ongoing public debates around the world are reexamining the role of the museum in contemporary societies, and causing institutional changes. Contemporary museums are always in a 'period of transition,' and attempts to renew them are continually made. As with previous times in museum history, the present is a complicated and complex period, affected by a range of contradicting demands made on the museum: to be representative, to consider political thinking, collecting, and display practices, issues of representation, and the contemporary world in which we live and which links us in new ways.

Music: Anthropological Aspects

Veit Erlmann, University of Texas at Austin, Austin, TX, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The article surveys the main trends in the anthropological study of music from the 1980s to the present. These trends are as follows: (1) music as culture and the mediation of social process, (2) music as discourse and the nature of musical meaning, (3) music and identity, (4) music and modernization, (5) music and technology, (6) music and knowledge, and (7) music as sonic practice.

Anthropological aspects of music are the main object of ethnomusicology and include all phenomena pertaining to music as a social and cultural activity. The study of the anthropological aspects of music is concentrated in the following main theoretical areas: (1) music as culture and the mediation of social process; (2) music as discourse and the nature of musical meaning; (3) music and identity; (4) music, modernity, and globalization; (5) music, media, and technology; (6) music as knowledge; and (7) music as sonic practice.

Anthropological aspects of music include all those elements pertaining to music as a social and cultural phenomenon. Currently, research on these aspects is concentrated in ethnomusicology. Other disciplines, such as musicology, cultural studies, media studies, and popular music studies, also increasingly take into account anthropological aspects, but have been slow in adopting more context-oriented approaches and ethnographic field methods. Anthropologists and social scientists, in turn, have generally shown only moderate interest in what the members of the societies they study hear, sing, or play. Within ethnomusicology, there exists a considerable plurality of paradigms, models, and methodologies, but the majority of scholars have approached their respective (geographic or historical) area of study from one or several of the following aforementioned perspectives: (1) music as culture and the mediation of social process; (2) music as discourse and the nature of musical meaning; (3) music and identity; (4) music, modernity, and globalization; (5) music, media, and technology; (6) music and knowledge; and (7) music as sonic practice.

Music as Culture and the Mediation of Social Process

Ethnomusicologists in the past have tended to treat music as somehow separate from culture, almost as a thing in itself. They assumed that culture was separated into different spheres such as politics, economics, and so on, each of which could be brought into some sort of relationship with music. According to one approach inspired by British social anthropology, ethnomusicology was the 'study of music in culture' (Merriam, 1964), with culture being little more than some ill-defined social context and music having the function of somehow maintaining the coherence of society. Another approach, modeled on the ideas of Ruth Benedict (among others), saw each society as being constructed around a fundamental principle or pattern that was then imparted to various cultural realms such as religion, art, music, and so on. Thus, Charles Keil, in a classic study of African music, found among the Tiv of Nigeria an 'expressive grid' that manifested itself in the circles, patterns, and structures of Tiv handicrafts, architecture, and songs (Keil, 1979).

Since the 1980s, scholars have begun to study music as culture. Influenced by the work of anthropologist Clifford Geertz and what has been called the 'interpretive turn' in the humanities and social sciences, researchers are thinking about music not so much as a secondary reflection of a more essential social structure or reality than as itself being a social activity mediating other social processes. Instead of gaining its meaning by somehow becoming part of a context, music itself is a context through which other forms of equally primary activity achieve meaning (Herndon and McLeod, 1981).

This new direction had three major consequences for the anthropological study of music. The first is that music makers and their music become dynamic forces, actively intervening in the shaping of cultures that are no longer seen as more or less coherent totalities or realities. The focus on culture as a heterogeneous field of conflicting forces shifts the attention from music as a product, a static expression of collective identity – as in 'the music of the Zulu,' 'music in village X,' and so on – to music as a process, as a mediating agent in the overall process of cultural negotiation. Or, as prominent British ethnomusicologist John Blacking put it, music was not only 'humanly organized sound,' but also 'soundly organized humanity' (Blacking, 1973).

The second consequence concerns the nature of scholarly knowledge and discourse about 'other' musics. For the reformulated critical disciplines, truth could no longer be something that was found from a neutral and distanced position. Following Edward Said's argument in his seminal book *Orientalism* (1979), the point of scholarship is not to deliver the 'true' other. Difference can no longer denote the distance between cultures such as the West and the East, just as it no longer refers back to an overarching scholarly (presumably Western and objective) frame of reference. Rather, difference, in the new disciplines, means the interplay of a multitude of competing and juxtaposed discourses. An example of this approach is Martin Stokes's study of Turkish *arabesk* music (1992). This style of music, popular with the marginalized urban masses, is more than the result of the stylistic development of Turkish folk music. It is part of a 'cultural field' in which different musical styles are best understood as 'different ways of talking about music' (p. 50).

Music as Discourse and the Nature of Musical Meaning

The third consequence, finally, of the 'interpretive turn' in ethnomusicology is the idea that musical meaning is no longer seen as being intrinsic to its sonic structure – a viewpoint still prevalent in musicology as late as the 1990s. Rather, musical meaning, like the meaning of a novel or a poem, materializes only in the act of experiencing music. Like a 'text,' a piece of music must be 'read.' And just like the meanings of a written text are not fixed in the text but are the result of discourses of which authorial voice and intention are one of many, the meanings of a musical performance are constantly changing and emergent, depending on the social structures and power relationships they help to define. The shift in musical scholarship from structural analysis to the interpretation of music as discourse occurred parallel to another significant development in anthropology and sociology in the 1970s: the emergence of theories and ethnographies of performance. On the basis of Erving Goffman's work and Dell Hymes's pioneering essays on the ethnography of speaking, anthropologists like Victor Turner, Richard Bauman, and James Fernandez began to examine the way in which performance contexts, events, and genres shaped communication and social action.

They were followed by numerous ethnomusicologists for whom the question of music's meanings and affective power became intimately tied to its real 'life': its relations with other forms of behavior and expressive culture, the interaction between performers and their audiences, as well as the unpredictability, and often improvisatory and playful nature, of music making. But whereas scholars such as Turner stressed the communal, ordering functions of performance, researchers are now more interested in the potential of musical performance for prompting change and resistance.

In line with these developments, scholars have also increasingly turned to the human body as the primary site for the construction of musical meaning. While earlier studies were based on a notion of the body as a biological given and, hence, stressed the physiological aspects of music making, recent studies posit the body as a cultural phenomenon, no less susceptible to and dependent on meanings than other spheres of human practice (Muller, 1999).

Music and Identity

The waning appeal of discourses that take stable notions of music and culture for granted have led scholars to reexamine the relationship between identity and music in a new, rather more skeptical light. Ironically, it is because of the fact that the growing isolation of the individual in modern society has generated new forms of collective identification – new nations, 'neo-tribes,' and new religions – that the time-honored interest in nationalism and ethnicity as the chief bases for music making has experienced something of a revival.

Of all the articulations of identity currently studied by music scholars, the modern nation-state and various types of nationalist discourse have probably commanded the most attention. Although studies of small-scale, mostly rural communities remain important locales for the ethnographic study of music, it is the contestations and entanglements linking the nation-state with multiply determined cultural practices that have become the object of the most sustained scrutiny undertaken to date. A rich literature on the new popular musics of the developing world – and, to a lesser degree, the advanced countries of the West – demonstrates how musical practices in the post-colonial world often disrupt the putatively homogeneous times and spaces of the nation-state, but at other times exist quite comfortably alongside nationalist agendas. In most cases, however, both positions blend into each other, often producing new exoticisms and articulations of racial or ethnic inclusion or exclusion (Guilbault, 2007; Sutton, 2002). Israeli rock influenced by Arabic music, for instance, celebrates an 'other' quite blatantly at odds with the images of backwardness that the Israeli majority projects of the Palestinian minority, yet at the same time it takes a stable 'Oriental' identity as its reference point (Regev, 1986). Conversely, some music have also been shown to lend themselves to more pliant forms of identity. This is perhaps more typical of the conflicted relationship between the nation-state, nationalist ideology, and cultural practices in diasporic communities. Thus, the music of black Americans is a product of the slaves' encounter with the West and, at the same time, has emerged in opposition to modernity (Gilroy, 1993). It may thus serve as a model for what Gilroy calls anti-antiessentialism, a critique of the oppressive history and racial injuries caused by the 'host' country that refuses to let go of memories of collective identity even where it resists grounding them in a direct genealogy rooted in the African past.

In some contexts, the nation-state may also come to the rescue of cultural diversity. Tanzania, for instance, is one of several countries that have tried successfully to promote 'national' musics by reserving some 85% of the music content on its national broadcasting service for local music products. But here, as in many other cases, the definition of what counts as representative of Tanzanian culture rested in the hands of the Swahili-speaking minority dominating the state apparatus (Wallis and Malm, 1992: 113–114).

Race and ethnicity are perhaps the second most studied forms of identity in ethnomusicology today. Deeply intertwined with nationalism, but also often standing in opposition to nationalist discourses, racial and ethnic identities are frequently seen to be most effectively asserted in the symbolic domain, such as in music. There are many reasons for this close nexus between ethnicity and music, but one of them is the fact that assertions of racial pride are voiced from marginalized social groups whose access to alternative cultural resources and power bases such as economic wealth is limited.

Processes of class formation, by contrast, and the musical construction of class consciousness have lost a great deal of their former appeal, primarily because the evidence gathered does not sustain the Marxist notion of a material base determining a suprastructure of ideology and culture. This lack of evidence was particularly pronounced in those areas where working-class cultures with pristinely defined contours failed to develop, as in much of the 'Third World,' or where they were about to disintegrate, as was the case in most of the advanced economies of post–World War II Europe and North America (Hebdige, 1979). By contrast, recent years have seen a growing interest in the formation of somewhat more fluid identities and

in the permeation of cultures considered to have once been 'premodern' with bourgeois values and practices. Under the impact of Antonio Gramsci's notion of 'hegemony' and Pierre Bourdieu's concept of 'habitus,' ethnomusicologists during the 1980s reassessed colonization and Westernization as projects that entail domination and acquiescence and that do not always occur along neatly separated lines of class or racial identity (Erlmann, 1999).

The notion, finally, that all identities are also gendered identities has greatly invigorated anthropological research on music and dance (Cowan, 1990). Although the idea has been familiar to ethnomusicologists for some time – much more so than to musicologists, whose subject until the 1980s seemed to be an unquestioned male one – recent scholarship has emphasized the negotiated character of sexual identity and the way in which music intervenes in the construction of such identities (Koskoff, 1987). As a recent study of the music of Maghrebian immigrants in France has shown, for example, *rai* performers and audiences construct complex identities around notions of sexuality, romantic love, and adolescence that are inspired by Western liberal ideals of gender equality (Gross et al., 1996). At the same time, these performers reproduce more traditional images of Arabness. While female singers often advocate more freedom for women, the jackets of their cassettes reproduce clichés of a more subdued kind of femininity and the ideal Arab woman.

Finally, an important focus that emerged from the current interest in identity and that undermines even further conventional notions of stable collective and individual identities – and the merely passive role of music in 'expressing' these – is the rather diverse set of practices circumscribed by terms such as diaspora, travel, migrancy, immigration, and displacement. Since the beginning of the 1990s, all these practices have been dealt with to some extent by ethnomusicologists (Turino, 1993), but musicologists and students of popular music have also increasingly committed themselves to exploring the interchange between music and the shifting boundaries of communities and audiences caused by large-scale movements of people. Furthermore, the spaces that people traverse as tourists, migrants, refugees, or touring musicians are all too often depicted as though they were bounded sites that are already filled with sound, and they are much less frequently depicted as multiply overlapping contact zones in which identities and musics are always blurred and emergent.

Music, Modernity, and Globalization

Most scholars now agree that music everywhere have been drawn into the maelstrom of modernization and, more often than not, have themselves become effective agents of modernization. While these scholars have as yet to arrive at a shared definition of modernization and modernity, it seems that the debate has centered on a series of intertwined issues and concepts. The first of these issues is globalization. Much of the discussion about globalization grew out of the concern with displacement and entailed a vigorous rethinking of the interrelationship between music and locality (Stokes, 1994). While previous scholarship tended to assume a relatively static fit between place, spatial identity, and music, an equation that often enabled scholars to produce richly detailed, empirically grounded narratives of local identity and music making (Finnegan, 1989), some researchers have gone one step further in examining locality as something that needs to be created in the first place. In a study of Nigerian *fújì* music and *oríkì* praise poetry, Karin Barber and Christopher Waterman (1995) show that while performers of these genres draw on a multiplicity of external sources to imagine densely local worlds, the emergent sense of locality is not simply stemming from any given body of materials or traditions. Rather, the "ultimate goal of any performance is to intensify the presence, image and prospects of local actors" (p. 243). Although it cannot be ruled out that Yoruba musical productions of place may be driven by the same agendas that underlie movements of national and ethnic purity, Barber and Waterman insist on the hybrid underpinnings of such assertions of local identity.

Moreover, the spaces in which scholars of popular music study and work are no longer necessarily such rather abstract entities as cities and countries. Increasingly, other spaces, such as recording studios, malls, music departments, and taxis, are becoming sites of inquiry.

Another aspect of modernization that dominates current debates is the power of capitalism and commodification to transform 'traditional' cultures, and the capacity of the Western mass media to shape the collective imagination of large populations. Some critics such as French sociologist Jean Baudrillard have tended to think about global cultural flows in rather uniform terms, positing a regime of simulations and simulacra as an all-embracing system. In line with this reasoning, some music scholars have taken a rather sinister view of global musical production at the end of the twentieth century. Steven Feld draws on Gregory Bateson's term 'schismogenesis' to think through a set of escalating relationships marking the production and consumption of music on a global scale. Schismogenesis is a process through which the interplay between essentially dissimilar but mutually appropriative actions may lead to a closer symbiotic interdependence of both sides, to the point that they may even become incapable of self-correction and get caught up in closed circuits of repetition (Feld, 1994). Ultimately, what results from this scenario is a gray out of a new type. As discourses of authenticity and difference assert themselves and activities of commercial appropriation in turn get more overt and outrageous, some kind of 'fusion of the parties for mutual business gain' becomes likely (p. 273).

Others scholars, by contrast, appear to equate 'Third World' cultural practices with antihegemonic agency per se, stressing the potential of music to maintain the heterogeneity of the world's cultures in the face of Western media dominance (Lipsitz, 1994). The majority of scholars, however, have taken a more nuanced position toward the role of culture in reflecting and mediating global relations of power, and numerous theoretical interventions have emerged in recent years that seek to provide new conceptual tools and models with which to grasp the twists and turns of global musical flows (Manuel, 1993). Mark Slobin, for instance, in an attempt to account for the impossibility of representing both global generality and local specificity, has depicted the interplay of various 'micromusics' in the West as a kind of 'interculture,' a constant oscillation between the pressures of the 'supraculture' and the contention of various subcultures (Slobin, 1993).

Finally, a handful of studies have attempted to view the making of globally connected identities as a two-way process in which center and periphery are constantly confused, and in which the West is just as much an 'other' of Africa or Asia as Africans and Asians have been the 'others' of Europeans (Erlmann, 1999). This includes greater attention to the agency of those (predominantly Western) 'global' figures, such as Paul Simon, Peter Gabriel, Quincy Jones, and Mickey Hart, whose practices and discourses are more than just manifestations of some anonymous capitalist world system or the global music industry.

Music, Media, and Technology

If anthropology's time-honored notions of identity and belonging and their intimate association with meaningful and largely homogeneous cultural practices by the 1980s were increasingly being viewed with skepticism, so too did ideas of unmediated individual or collective creativity rooted in genius or tradition come under fire. The emergence of digital technology, the decline of state-controlled media as the sole authority on what constitutes the public good, the legitimacy of power, or the value and meaning of cultural practices, followed by the rapid expansion during the 1990s of deregulated and new media such as the Internet, promised new levels of access, participation, and diversity, in turn leading to a reevaluation of the conditions under which people interact with music. While such broadened arenas of interaction – often all too hastily equated with Western-style liberal democracy per se – may serve to strengthen existing identities and communal boundaries threatened by global flows of capital, frequently they also create new affiliations and new distinctions based on choice and taste rather than state-mandated ideologies and allegiances. Much of this turn toward technology is owed to the pioneering efforts of students of popular music to understand popular music through the prism of its media and technology a priori rather than the structural or historical analysis of works. At the same time, much scholarship within the field of popular music studies prior to the 1990s has been prone to overtheorization, often at the expense of more sustained empirical engagement with embodied uses of technology within specific locations and among historically determined actors. However, by the early 2000s, many scholars working in popular music studies found common ground with ethnomusicologists and anthropologists (and, to a certain degree, music theorists) as these turned to the specifics of music technology as part of socially mediated and locally embedded cultural practices (Greene and Porcello, 2004; Lysloff and Gay, 2003). The result of this convergence of disciplines is a growing body of literature on such diverse topics as the musical impact of the rise of the audiocassette in India (Manuel, 1993), the recording studio as a site of different forms of social interaction in South Africa or Indonesia (Meintjes, 2003; Wallach, 2008), the home studio in the West (Theberge, 1997), the culture of sampling in hip hop (Schloss, 2004), the politics of mixing and sound engineering in Brazil and Jamaica (Moehn, 2012; Veal, 2007), and the history of the MP3 (Sterne, 2012). At the same time, other media that have long been staples of research in social history, media studies, and cultural studies such as radio and television have yet to become the object of sustained attention among ethnomusicologists.

While many of these technologies might be seen as perpetuating the hegemony of Western standards of aesthetic and economic value, in many cases they also support alternative forms of musical creativity, income-generating strategies, audience involvement, and social distinction. At the same time, the rise of MP3 as the standard format for sound reproduction and dissemination fundamentally affected music's role in mediating social structure and practice. While the effortless and instantaneous dissemination of sound files across cultural, social, and national divides opens up a space for envisaging new communities, this creative potential is also severely hampered by new legal frameworks that reduce what had previously been owners to mere 'users.' Increasingly, disputes over aesthetic value, cultural memory, and public access to culture are subsumed under legal battles over intellectual property rights. The ever more forceful intrusion of intellectual property law into every aspect of music making and consumption is the subject of intense debate within media studies and among activists in the West (Burkart, 2010), with anthropologists and ethnomusicologists beginning to consider the impact of international intellectual property regimes on local communities on the fringes of the global economy, attending to issues such as piracy, cultural rights, and heritage (Weintraub and Yung, 2009; Erlmann, forthcoming).

Music and Knowledge

The anthropological study of music, much like other projects within the humanities and social sciences, since the early years of the twenty-first century has come under growing pressure to demonstrate its 'impact' in a global order of knowledge dominated by concepts of 'efficiency' and economic viability. In this climate, music scholars are increasingly looking to the sciences for inspiration and legitimacy. Buoyed by the popular appeal of the neurosciences and narratives about the inherent compatibility of music and mathematics (the 'Mozart effect'), scholars from the 1990s were particularly drawn to the history of science. Having regained widespread acceptance from the 1980s, the notion that discovery and knowledge are culturally contingent and that the arts and the sciences are closely intertwined proved attractive to a field steeped in a variety of epistemological traditions from Buddhism to German idealism and with deep affinities to mathematics and the study of nature at large. Thus, several historians of science have explored the history of acoustics not as the foundation of but as being embedded in musical practice (Gouk, 1999; Jackson, 2008; Erlmann, 2010).

Yet the notion that the relationship of music to things like cognition, consciousness, and affect, instead of being the exclusive domain of psychoacoustics or music psychology, might be culturally determined and that, hence, this relationship would be open to anthropological or ethnomusicological inquiry only took root toward the late 1990s. The work of anthropologist and ethnomusicologist Steven Feld provided a significant stimulus to this line of thinking (Eisenberg, 2010). Departing from and critically responding to Canadian composer Murray Schafer's work in acoustic ecology (Schafer,

1977) and reflecting on his own fieldwork in the rich acoustic environment of the Kaluli living in the rainforest of Papua New Guinea, Feld (1982) in a series of writings and audio-collages (the latter being called, after Schafer, 'soundscapes') intervened in anthropology's and ethnomusicology's ongoing crisis of representation not so much by providing readers and listeners with a sense of what Kaluli music *is* but, rather, by engaging in a written and sounded dialogue with Kalulias they musically and sensorially construct the world around them (Feld, 1991, 1996).

Music as Sonic Practice

One of the most promising developments of the 2000s has been the emergence of sound studies, a field of inquiry that draws much of its rationale from a growing sense of discomfort with 'ocularcentric' constructions of modernity (Jay, 1994) and the hegemony of the visual in a wide range of academic disciplines, but particularly within cultural studies. Concerned with a broad spectrum of sonic phenomena from ring tones to urban noise to the history of sound compression, sound studies has been influential in decentering music from its privileged position at the heart of (Western) romantic and modernist aesthetics. Music instead becomes one among many sonic practices. Although the roots of this 'auditory turn' can be traced to a variety of post–World War I philosophical traditions such as the French Annales and the Histoire des Mentalités schools of thought, other developments from the 1990s also contributed to this trend, such as a shift from the conventional radio feature or *Hörspiel* to experimental sonic practices such as 'soundscapes' and sound art (Samuels et al., 2010), the emergence of film sound studies (Altman, 1992; Chion, 1994), and the turn within anthropology toward the senses (Stoller, 1989; Classen, 1993). Among the latter, the 'denigration of vision' (Jay, 1994) was particularly pronounced, growing out of a sense of disaffection with the interpretive turn led by Clifford Geertz and its emphasis on cultural practice as a form of intertextuality and, hence, on anthropology as 'reading' (Howes, 2003: 17–22).

Anthropologists' rekindled interest in sound and hearing for the most part excluded music, with several influential studies having appeared on sound in Islamic devotional practice (Hirschkind, 2009) and the soundscape of northern Nigeria (Larkin, 2008). Ethnomusicologists, for their part, soon followed the lead of historians and anthropologists in studying listening practices as sites of identity formation, the materiality of acoustic communication, and the politics of noise in urban settings (Erlmann, 2004). Between them, these new directions play a significant role in drawing attention to contemporary music's changing place on a continuum of sound, noise, and multisensory practice, thus widening the scope of the anthropological study of music in a rapidly changing world.

Abstract

History of music, or the historiography of music (music history) is a synonym for that segment of musicology referred to in recent decades as 'historical musicology.' Methodological approaches peculiar to the history of music arise from the transitory nature of music as a performed art form, musical notation (which was never obligatory for those belonging to the elitist social group), and the acoustical documentation of voices and sounds since the invention of the phonograph in 1877. The representation of history within the discipline, music's beginnings, the nature of historical musicology and its methods, the concept of the 'relative autonomy' of music history within the scope of art history, and recent developments are examined, in addition to the tension between local and global historiography, the focus on Western art music ('eurocentrism'), and finally political or nationalistic implications.

'History of music' signifies the sum of all musical or music-related events in as much as they have been documented or handed down through time. In particular, it refers to the historiography of music (music history) and is a synonym for the discipline of musicology. In recent decades it has come to designate that part of musicology referred to as 'historical musicology.'

History and Representation

The panorama of cultures, with their divergent concepts of music and history, are too multitudinous to be adequately and equitably considered here. A review of the world's oral and written musical traditions, whether they be Indian, American-Indian, Chinese, Australian-Aboriginal, Japanese, Ewe, Near-Eastern, or Central European, would only culminate in the emptiest of generalizations to compare their individual courses. For reasons of expediency, therefore, the following remarks refer to the history of music as perceived from the perspective of Western culture and are restricted to its tradition.

Three characteristics of music determine and modify questions concerning historical data, documents, and sources, modulating thereby the various approaches to the history of music. (1) By necessity, the transitory nature of music as a performed art form does not engender an immutable artifact for permanent view, and, in contrast to the visual arts, is dependent on reproduction and representation. This contributes to the tendency to perform and listen to music as though it would be permanently present. In fact, performing or listening to music from an earlier period decomposes the historical distance between the period in question and the present time. This impulse to dispossess music of its history may in some instances lead to the radical inclination to regard music as a natural phenomenon rather than as a historical one. (2) Musical notation was an early invention. Two different kinds were already established in Greek antiquity, most likely for educational purposes and not for the preservation of music for future generations or for performances. This also holds true for the earliest stages of polyphony in the Middle Ages, which went hand in hand with the beginning of notational practice and ultimately led to the types of scores now familiar to us. Before printing was invented, it can scarcely be claimed that musical notation produced works as texts comparable to written texts, such as the *The Odyssey* or *The Iliad*. And while illiteracy and education are by nature contradictory, musical illiteracy has remained a socially tolerated phenomenon; someone who is unable to read music, will not be ostracized from an elitist social group. In popular music circles musicians have never been required to possess the ability to decipher musical notation. (3) With Edison's invention of the phonograph, voices and sounds could be acoustically documented for the first time. Due to the omnipresence of music in today's popular culture and the recording industry, one can easily forget that this 'kopernikanische Wendung' in music history took place just one century ago. In 1886 Friedrich Nietzsche asserted that music is the latecomer of every culture (*Menschliches, Allzumenschliches II*, Sect. 171). Although this corresponds to the romantic conviction that music is the youngest of the fine arts it seems to contradict the Western tradition that ranked music theory among the earliest individual academic disciplines, together with arithmetic, geometry, and astronomy. This was the case in the Greek *enkyklios paideia* and later in the *quadrivium* of the medieval *septem artes liberales*. To the degree that music is more often associated with emotional and spiritual qualities than with intellectual or physical ones, the reconstruction of the history of sound is no less precarious than the history of the emotions themselves. Both fields are predominantly dependent on a systematic or experimental approach rather than on a historical one. And in contrast to archeological sites or the visual arts, the historical foundations of music are ultimately of less interest within the context of the essentially personal need for music.

Considering Music History and the Beginning of Music

History has always played a certain role in speculations about the theoretical basis of music. The historical account of music in (pseudo-)Plutarchus's *De musica* from ca. AD 100 weaves together mythological and historical names (that cannot be clarified in each instance) before turning to the matter of 'old

music,' regarded as holy and good, and its succession by 'new music,' seen as degenerate and decadent. Aristophanes and other contemporaries maintained that this transition took place in the late fifth century BC. Twentieth-century historians still adhered to this model. Greek myths and medieval legends based on biblical narrative that once explained and interpreted the origins of music have today been replaced by 'scientific' theories that biologically and genetically construe the earliest stages of the development of music, whether beyond written traditions or in pal eontological respects. One may ask whether modern speculations as to music's prehistoric inception are more reliable than Ovid's report of Pan's invention of the syrinx (*Metamorphoses* I, 689 ss.) that signaled the beginning of another *ars nova*, or more insightful than the lemma handed down since late antiquity that states Pythagoras as the inventor musicae, claiming that he was to have found an explanation for the phenomenon of consonances and therefore to have 'invented' music theory.

By 1700, book titles espousing the history of music appeared throughout Europe (e.g., W. C. Printz, *Historische Beschreibung der Edelen Sing-und Kling Kunst*, Dresden, 1690; G. A. Bontempi, Historia musica, Perugia, 1695; P. Bourdelot and J. Bonnet, *Histoire de la musique*, Paris, 1715). In all cases, the point at which the history of music is seen to begin is dependent upon the historiographical premise that has been taken. Some scholars proceed from early organized polyphony around AD 900; others go back to monophony (Gregorian chant). The belief that ancient Greek music need not necessarily belong to music history's canon is in large part due to the decrease in the knowledge of the Greek language in the twentieth century, with the result that it is subsequently relegated to the fields of ethnomusicology or anthropology (cf West 1992, p. 3). Thus, what was still regarded to be the foundation of European culture and humanistic tradition in the nineteenth century has been cut off from the history of Europe.

The Discipline and its Methods

The rise of historicism in the nineteenth century brought music history (together with art history) as an academic field into the university, a development that began primarily in German-speaking countries. The history of music quickly became an essential component of both the theoretical and practical study of music. Together with specialized research institutes, the academic discipline increased in German universities after World War I, while the wave of emigration following 1933 played an exceptional role in its advancement in the USA. Since World War II the discipline has grown inside and outside Europe, and today is established in universities worldwide. Aside from biographical studies and philological efforts (such as editing scores and theoretical texts on sources), music history's chief methodological approach has been to examine the history of style, or more recently, genre. This is narrowed down further to the history of composition or individual works. Special attention has been given to the history of reception throughout the last decades. Even with respect to essentially synesthetic productions, such as opera or stagings within the multimedia landscape, the score remained the music historian's most important source at hand. Up to the present time, the predominant individuals of interest for historians have been composers, regardless of how prominent a performer, whether singer, conductor, or instrumentalist, may be. This is also the case within the history of performance practice (impulses coming from the UK), which attempts to reconstruct performance style within any given age independently of the work of individual interpreters. Compared to music history's concentration on composers and compositions, adjacent fields such as the history of music theory and of music aesthetics, and the archeology and iconography of music have assumed less prominent positions. This holds true for the relationship between the history of music and history as well. For example, while writings on the history of sacred Christian music are often aligned with related areas such as the history of liturgy, churches, and religion, contextualizations within social and political history remain rare. Supported by the romantic notion of *Kunstreligion* (the substitution of religion by the arts), the ideology that positions music in an apolitical, internalized, subjective domain strictly separated from social and political conditions has not yet been fully overcome.

Boundaries

The history of music has pertained and, in large part, still pertains to Western music, if not exclusively. The periodization of earlier epochs (the Middle Ages, the Renaissance, and Baroque) has remained comparatively stable; thereafter, less so. The history of music is patterned after conceptualizations similar to those used in general historiography (whether in the framework of *Geistesgeschichte*, social, or cultural history); the philosophy of history; and the fundamental concept of permanent progress (innovation and its aesthetic equivalent, originality) and cyclic forms (such as ascent, climax, and decline). In spite of how commonplace the expression 'occidental music' (*abendlän dische Musik*) is, a history of European music in which local, regional, and national traditions are treated as a unity within diversity – in accordance with the standards of the modern European Union – has yet to be written. Historians who specialize in the musical culture of their own regions often lay claim to the concept of occidental music, and yet upon closer scrutiny, the traditions of other countries are comfortably overlooked. In the subtext one can ascertain that the inclusion of music from the Byzantine empire (with consequences for Eastern European music) and from the Americas within the occidental circle is questioned. The post-Wagnerian composer Hans Pfitzner (1926, p. 193) compared music's historical course to the upbringing of a boy whose first nurse was Dutch, who then lived for a season in Italy before making his home in Germany around 1750. Music historiography, dominated by the ascendance of nationalism in the nineteenth century, has been influenced by national historiography. Some music historians' nationalistic stance relies on a conception of music history in which consecutive composers are threaded onto a string of pearls, neither allowing for diversity or pluralistic considerations.

'Relative' Autonomy

Music historians who view the history of music within the scope of art history tend to view favorably the idea of

a '"relative autonomy" of music history' (cf Dahlhaus 1983, Chap. 8). This concept focuses on questions of style, genre, and composition without giving credence to their contextual arena–an idealistic interpretation of art music that boasts of a pragmatic concentration on musical components at the cost of music's isolation from society, economy, and politics. The idea of autonomy maintains that (1) art is independent of life and (2) music history is made up of a sequence of masterpieces written by heroic composers of genius, whose musical innovations and originality are synonymous with progress. This progress is often associated with decline in differing degrees up to the present time: while contemplating the grand summits of art music, no thought should be squandered on the valleys. As can be expected, Marxist writers have explicitly opposed this view (cf Knepler, 1977, p. 462 ss.). Art and social histories were often strictly and programmatically opposed to each other; particularly in the tradition of Hegel, dominant in German musicology, this led to a disengagement between music history and history in general. The historiography of Western music has remained the historiography of an elitist art form. In spite of its universal popularity, Beethoven's music has never belonged to the realm of popular culture (one notable exception being the *Ode to Joy*, used as the anthem for the European Union). Popular music–written for the day, not for eternity–has socially, politically, and historically been the most effective type of music throughout the ages. Music historians seldom participate in the methodological discourses of historians. Likewise, the historian's rare stand on musical matters, owing to a lack of technical skills or detailed knowledge, is similar to the philosopher who eschews discussions on music in their aesthetic writings. None of the famous historians, therefore, focused on music or, particularly, music history as a methodological paradigm, and in spite of the general increase of interdisciplinary research, historical musicology and history rarely cooperate.

Recent Developments

Music history, perceived either as the history of Western music in general or its various national entities, came to be questioned in the second half of the twentieth century. In the USA a discussion about whether its music history should solely be defined from the European perspective has emerged. A front-page article of the *New York Times* entitled 'Ibn Batuta and sitar challenging Columbus and piano in schools' on 12 April 1989 asked whether university professorships for piano should be replaced by those for sitar. Jazz and other forms of popular culture excluded from traditional historiography have been seen by some to pose a threat to the canon of classical music heard in Carnegie Hall and at the Metropolitan Opera. 'Eurocentrism' in music has come under critical scrutiny in recent years. Ethnomusicologists increasingly bemoan the dominance, even hegemony, of Western music as it spreads globally through radio and recordings. This new wave of cultural colonialism is seen as a potential annihilator of the last traces of 'original' music cultures. In extreme cases, ethnomusicologists deny history in music altogether if the related culture in question does not reflect the concept of history, or where a lack of observable change has led to an 'almost absolute stability of the musical cultures of non-Western societies,' a view modified by major scholars (Nettl, 1983, p. 172). Although 'world music' is the slogan of the day, the idea of a universal history of music is seen to be obsolete or, due to the plethora of materials, unmanageable. The relevant UNESCO project begun in 1979, *Music in the Life of Man*, retitled in 1989 *The Universe of Music. A History*, has produced programmatic statements rather than results. Conversely, the controversial search for 'uni versals' in music is generally conducted in a non-historical fashion. 'New musicology,' which began in the USA in the early 1980s, directs its attention to gender issues and the music of minority groups, and emphasizes a contemporary approach to criticism in which the role of history has yet to be fully defined. The phrase 'new historicism' has entered into the discussion of late (cf Stanley, 2001).

Identity Exchanges and Modern Mythology

The current global fashion and passionate search for cultural and national identities presents some dubious consequences for music history. If one attempts to decipher what is specifically 'Italian' or 'American' in a piece of music, the answer will remain arbitrary by definition, since sounds cannot signify unequivocal and indubitable meanings. An example of one such identity crisis can be found in Austria. Viennese classical music, denoting the music of Haydn, Mozart, and Beethoven, has long been considered to be a paradigm of, if not synonymous with, German music. In 1947 Albert Einstein stated that the 'concept of German music' itself has come to rest on the works of these three masters (cf Einstein, 1992, p. 261). Austrian historiographers of music have now come to emphasize their own musical identity as being distinctly different in substance from a German one. This recent dichotomy is all the more curious since Austrians have frequently been eager to discern the German identity in their Austrian composers. Now Beethoven regains the status of an alien immigrant at best (cf Flotzinger, 1997, col. 1201). Hitler's former Reich's Music Chamber President, Richard Strauss, revealed yet another astonishing conviction shortly after World War II. On May 20, 1946 he admitted to his devoted friend and historiographer, Willi Schuh, that in all likelihood cultural historians, German patriots, and the Jewish press would be less than pleased with his tenet that 'political Germany *had* to be destroyed after it had fulfilled its world mission: the creation and perfection of German music' (Strauss 1969, p. 89). Of course, the composer regarded his own music as this ultimate fulfillment, as the end of music history. Uniting the idea of the end of art and the end of politics, his vision placed all future music in a state of a *post histoire*.

Nowadays, music composed just a few years after Strauss' remarkable statement, whether serial, electronic, or chance, is considered classic. The histories of all musics have been subject to various readings throughout the course of time, often stemming from a national, ethnic, or otherwise political intention. The genesis of one of the most significant twentieth-century forms, jazz, has been alternately depicted as originating in Africa, Europe, and America. And it is in the New World that the search for a national musical identity during the first half of the twentieth century failed to produce a national school of composition. 'Each composer found his own way,' and 'perhaps this is the way it should be in America' (Hamm, 1983,

p. 459). Perhaps this maxim could on occasion be applied to the realm of music history as well.

Abstract

Alva Myrdal was a Swedish social scientist, politician, and feminist who made an intellectual contribution in several fields: child-friendly education, welfare state theory, women in the labor market, international development, and disarmament. A prolific writer and researcher, most of her life was spent working as a representative of the Swedish Social Democratic government in national and international contexts, including a period (1949–55) as Director of Departments at the UN (Social Affairs) and UNESCO (Social Science). Her most famous works are 'Nation and Family' (1941), 'Women's Two Roles' (with Viola Klein, 1956), and 'The Game of Disarmament' (1976). She received the Nobel Peace Prize in 1982.

Alva Myrdal: A Passionate Engagement for Social Justice

Alva Myrdal has been variously described as feminist, social reformer, welfare theorist, diplomat, sociologist, politician, human rights activist, writer, ambassador, cabinet minister, and Nobel Peace Prize winner – indicating the breadth of her extensive contribution to public life. This broad contribution was largely framed by her active, lifelong membership of the Swedish Social Democratic Party during its long period of major welfare and educational reforms; by her leading international positions in various departments of the United Nations and international women's organizations; and by her many contributions, as an international diplomat, to world peace and disarmament. She was also a prolific writer and researcher who wrote extensively in both popular and academic contexts, on social and political issues ranging from childcare and working mothers to nuclear disarmament and superpower politics. All these varied activities in support of a more just and conflict-free social world were underpinned by her passionate faith in the possibility of a scientific, rational understanding of the relationship between the different domains of social and economic life (public and private) and their mutual interdependence. If we could only scientifically better understand what these relationships are and collaboratively resolve their inherent complexity, she argued, life could be free from cruelty and fear and be more openly, fairly, and humanely organized and managed.

A Feminist for Children

Alva Reimer was born in 1902 into a family of modest means. She soon came to share her father's interest in the work of the Social Democratic and Cooperative movements for greater justice for farmers and workers. Her early dreams of independence fostered a commitment to women's emancipation in all its aspects. She was already, as a child, a ferocious reader and writer, who found it a handicap that she was not a boy. Poor access to academic secondary school for girls and with little parental support for further study, she left school early with a qualification in commercial and secretarial skills that enabled her to support herself whilst completing her matriculation at a private tutorial college. She was only 17 years old when she met her future husband, the economist Gunnar Myrdal (1898–1987), with whom she shared a lifelong, intellectual partnership and had three children. At university she studied literature, languages, psychology, pedagogy, and sociology – some of these on grants alongside her husband, as Visiting Scholar in Germany, the United States, Britain, and Switzerland. For the first decades of her married life she also acted as hostess and intellectual sparring partner to her husband's friends in the radical intellectual circle surrounding the economist Gustav Cassel and the Stockholm School of Economics, whose younger members advocated a stronger role for the Government in economic relations. She developed a growing number of her own engagements, including those in the politically important Swedish Social Democratic Women's Federation, an organization, which throughout her life remained for her, an important intellectual and political platform.

In 1929 both Gunnar and Alva Myrdal became recipients of Rockefeller Fellowships – in her case to study social psychology, child development, and social work. Before leaving for the United States they spent a few months studying in London learning fresh (but in their minds, too class-ridden) perspectives on economics and reform. In the United States they were warmly welcomed and introduced to the best minds in their fields. Alva Myrdal drew inspiration from developments in family sociology and in the project-oriented urban sociology of the Chicago School. She was particularly influenced by the sociologists Robert and Helen Lynd, W.F. Ogburn, and W.I. and Dorothy Thomas, the latter becoming long-term friends. All were theoretically and methodologically concerned with the relationship between individual cultural perceptions and industrial and institutional change. The changing status and needs of children in democratic modernity was a topic of particular concern in the United States at the time, as were developments in scientific means of observing them, developed by the Viennese pedagogues Charlotte Buhler and Dorothy Thomas (both at the time at Columbia University Teachers College). There were also many opportunities during the year for networking with the politically influential professional women's organizations of the time. But the year of the visit was also the year of the Wall Street stock market crash and they encountered mass unemployment and large-scale

poverty in a political context of surprising passivity and inaction, despite a 'hands on' culture of political optimism. She returned to Sweden both enthused, and firmer in her conviction that something must be done to prevent such misery and that she could not, like some of the American academics she met, remain politically inactive.

One of her first actions on returning from America was to establish study circles for parents, based on courses she had observed in the United States, to help them become better informed about modern, child-friendly, child rearing practices. When her proposal for publically financed nursery schools was initially rejected by the Social Democrats, she gained the support of housing cooperatives for the creation of her own preschool teacher training institute, the Stockholm Pedagogical Institute for Preschool Teachers, to which she brought the latest international developments in child psychology and pedagogy. Another major engagement at this time became that of housing and the question of how it could be improved to support families, especially working women and children. Stockholm had in 1930 hosted an international exhibition, which saw the breakthrough of functionalism as a new radical architectural approach to the needs created by urban growth and the demands for the modernization of domestic life. Alva Myrdal, like many members of the Swedish radical elite at the time, was enthused and joined one of the architects of the movement, Sven Marklund, using her growing skills as a social scientist and pedagogue to put her own progressive ideas into practice. Her first published article was a polemic in support of collective service housing and its significance for a more democratic form of family life, with both men and women at work. She also wrote a much noted book on the nursery needs of city children and articles on the design of child-friendly pedagogical toys. The collaboration led to the construction of a block of flats in Stockholm, intended as a social experiment, which had communal eating facilities and well-staffed nurseries with modern, child-friendly equipment. The building itself, though much discussed, was not replicated largely due to costs – particularly for providing service staff – but also because of resistance from both men and women to its concept of a professionally organized, expert-led, family life. But the significance of child–friendly, state-supported, affordable housing with communal playgrounds and laundry facilities became generally accepted as a key plank in the Social Democratic Reform agenda. Her activism in the area of housing led to her serving as expert advisor on a major governmental commission on housing in 1935. Her feminism and visions for modern womanhood, expressed in numerous magazine and news paper articles on a range of topics relating to women's right to work, better working conditions whilst having children, and women's education, as well as her activities in various women's organizations, led to her chairing a government commission on women and work. Its 1938 report tried to present a more realistic picture of the needs of women, (particularly married women in the labor market) than was politically customary at the time. Her activities in the International Federation of Business and Professional Women led to her becoming its Vice Chairman between 1938 and 1947, and gave her a foothold amongst politically active women internationally.

Welfare Theorist for Families

Having since her youth publically argued for improved rights for women and children across all social classes, the impact of Alva Myrdal's theorizing became seriously influential through the publication of a book written jointly with her husband, on population policy and the declining birthrate in Sweden during the decades between the two World Wars (1934). The book affirmed her position as a major theorist of the welfare state and the social rights of citizenship. Through closely shared writings, the book brought together the Myrdals' earlier separate writings on economics and the family to form a major critique of liberal laissez faire and voluntary approaches to the maintenance of a basic standard of life for all. It also criticized a narrow Marxist view of historical determinism. Only the State, they argued, could provide financial security for all during periods of economic or individual hardship. But only a democratic State, inclusive of and responsive to its citizenry with respect to values, rights, and duties, could do so in a way that ensured justice and the preservation of individual freedom. In focusing on population decline, the Myrdals painted a picture of a society on the brink of decline with a poorly equipped citizenry, unable to support itself and its children,; and as a consequence a society unwilling to reproduce itself, given the cost of raising children and the need for women to earn wages. A policy of continued restrictions on the availability of birth control, they argued, would only reaffirm social misery and continue the population decline. For social policy to be effective, they argued, both economic and social factors must be preventively addressed through government planning based on up-to-date social and economic specialist expertise. The nation needed to take collective responsibility for children and their well-being. With a wholly man-supported family no longer viable for both economic and political reasons, children were also at risk of being neglected – an unsatisfactory state of affairs when future growth depended on their capacity for independence and learning. Children and youth should be treated as a national asset with their rearing, alongside that of health and education, collectively organized and supported.

Backed by a rich variety of economic and social evidence and influenced by their contact with American-style applied social science, this expose of a poor nation in decline became the focus of a national debate. An immediate bestseller, it proved a focal point for the development of the Swedish Welfare State during the reign of the Social Democratic Party before and after the Second World War. In response to the public debate generated by the book, the Myrdals both became members of the Population Commission established in 1935, which through its work provided the background to specific reforms. They should not, however, be given the full credit for these reforms. Many reforms were already on the agenda of the increasingly successful Social Democratic Party, which in response to the Depression had widened its electoral remit to include interests outside the industrial trade unions, to include farmers and lower-grade white collar workers, ideologically unified under the banner of Sweden as 'the people's home.' The radical enthusiasm with which the ideas were disseminated in a variety of contexts by both the Myrdals proved one of the catalysts for radical change. As

a catalyst, the book should also be understood as a reflection of their urgent wish at the time, to convince the Swedish population that the best weapon against the political instability, violence, and totalitarianism (that was spreading elsewhere in Europe at the time), lay in a shared solidarity for social democratic progress.

From the start their political vision attracted many critics who expressed anxiety about notions of social engineering 'from above'; warned about the over-reliance on professional 'experts' in execution; and deplored the arrogance implied in drawing up detailed norms for the domestic lives of ordinary citizens. Criticism was most forcefully expressed during periods of political opposition to the Welfare State, both from the political right and the left; and it also became particularly directed at Alva Myrdal, herself a housewife and mother. It took its most dramatic form when she was held responsible for the high number of sterilizations undertaken by Swedish doctors during the early postwar decades. Her general recommendations in connection with population planning were those of sterilization as a voluntary means of securing only 'wanted' children. She can be charged with naivety in assuming that when implementing the policy the medical profession would act as democratically and humanely as she envisaged. By the time this unacceptable medical implementation of a largely well-intended law occurred Alva Myrdal had left Sweden, and moved her visions of women's independence and better care for women and children to the international stage. Her trust in 'experts' declined, as her experience widened.

In 1938 Alva Myrdal returned to the United States to accompany her husband, who had become the recipient of a major research grant to investigate American race relations, and began to disseminate information about Swedish welfare reform to American audiences. Her book 'Nation and Family' (1941) which summarized early Swedish reforms in housing, nutrition, care of the disabled, education, contraception, child care issues, and their political rationale soon became a much be supported in a democratic context of individual equality. In this she noted that it was not the women themselves, but marriage as a social and economic institution that was the problem. This was a theme to which she would later return. On the strength of this book she was invited to lecture across the continent, particularly to women's organizations, to explain its major premises. After a brief return to Sweden during the early part of the war, she returned to the United States via a forced stay in Britain in 1941; during this period she wrote Swedish newspaper articles and later a book, about Britain at war, based on wide-ranging interviews and in-depth observations. This work, alongside a book with her husband about their experiences in the United States (1941), should be seen as an intellectual effort to support faith in democracy and free debate during the darkest years of the war.

Educationalist for Democracy

Though often highly critical of American competitive individualism, she maintained a strong belief in the long-term power of the American system of democracy to sustain and improve itself and the role of its common and secular education system. On returning to Sweden later in the war, she became deeply involved with refugee questions, particularly that of the educational needs of orphaned and displaced children. She founded and edited a multilingual newspaper for refugees and continued her regular, sharply prodemocratic, and antiracist contributions to the press. Her international engagement with education was strengthened in her appointment as Founder Chairman of the World Council for Early Childhood Education. She was the Swedish delegate to the ILO conference in Paris in 1945 at which the Declaration of Children's Rights was proclaimed, and she became Swedish delegate to the First General Assembly of UNESCO in 1946.

The combination of party activism, membership of various research commissions and women's organizations, and her growing fame as an expert in education led to Alva Myrdal in 1946 becoming a member of a fresh Social Democratic Commission on Educational Reform – the earlier ones having failed to reach agreement on how to modernize the traditional parallel school system. Her ideas are evidenced in its final, ultimately successful, recommendations of a common school for all Swedish children. This was not a new concept in Swedish educational debates, especially amongst elementary school teachers; but with her arguments drawn from international developments in pedagogy and her access to a variety of political platforms, she became a powerful champion who could speak with the voice of authority and expertise. For a Swedish audience she wrote on the John Dewey-inspired, progressive aspects of the American unified school system and its student-centered, more practical, and civics-oriented pedagogy. She also looked to Great Britain and its reforms to open opportunities for working class pupils. She strongly admired traditional Scandinavian adult education in its more democratic forms of study circles and home learning opportunities. The traditional Swedish school system was highly differentiated, ostensibly on the basis of ability, but in reality on the basis of class, gender, and geographical location. She campaigned forcefully in articles and lectures for undifferentiated, free, nine-year state schooling with a common curriculum of both theoretical and practical subjects. She gained support from women, teachers, and youth organizations in the party. There was also teacher support for better training in new forms of child-friendly pedagogies to foster individual autonomy and growth, especially the skills of democratic collaboration across social and vocational divides. War and its antecedents had made education reform a particularly urgent priority, with the German school system, which had been historically influential in Sweden, discredited for its pedagogy of obedience. Internationalism in the curriculum was to be fostered, including the universal teaching of English. Her originally utopian reform proposal gained acceptance, originally for a period of experimentation. The dual school system was finally abolished in 1957.

As so often before and after, in promoting education policy reforms also, Alva Myrdal chose to become fully engaged in the political process of ensuring the popular success of proposed reforms, enrolling sympathetic experts in her support – a strategy that made her open to the charge of social engineering, a concept that after the war gained increasingly sinister overtones. By the time Alva Myrdal returned to the topic of educational reform in the 1970s, as Chair of a report on equality presented to the Swedish Social Democratic Party, she presented evidence that students from privileged backgrounds,

and particularly boys, continued to make the best use of higher education and the career opportunities it offered, indicating that comprehensive school reform had not fully succeeded in all its aims. There was, she argued, yet more work to be done for educational justice to be achieved for women and working class children.

Social Scientist for International Cooperation

In 1947, Alva Myrdal left Sweden to accompany her husband, who had accepted a position as Executive Secretary of the UN Economic Commission for Europe, a key agency in postwar economic revival. Geneva was at the time a city in which, she as a married woman, was not allowed to work. When in 1949 she was offered the post of Director of the UN Department of Social Affairs, she accepted. This was her first full time employment and the highest post ever held by a woman within the organization. She saw this as a platform from which to continue her activism on behalf of women and children, but also used it as a platform from which to continue to propagate the importance of social science research and evidence. Though often highly critical of the politics of the United States and the failure of its politicians and academics to act in defense of its poorer citizens, she retained her conviction that the combination of its economic strength with its democratic creed placed a special responsibility on Americans to foster improvements in the everyday lives of citizens across the globe; and she saw the agency of the United Nations as a vital organization in the furthering of international cooperation. During the harsh years of the Cold War, US politicians were not always grateful for her loyalty.

After 2 years at the UN headquarters in New York she returned to Europe when she was appointed director of the UNESCO Department of Social Science in Paris. During her stewardship, a network of international social science associations was financially supported and organizationally facilitated with the hope that such associations would help advance an improved culture of social scientific approaches to social problems, particularly the democratization of access to information and its worldwide dissemination. She encouraged bibliographical initiatives and information overviews in specified fields, such as intergroup cooperation, access to education for women, migration, and racism. Her faith in social science research as a 'toolbox' of methods, in principle available to all as a means toward more effective and democratically derived solutions to social problems steeped in entrenched political and value conflicts, was forcefully expressed in a talk she gave at the School of Social Work at Columbia University (1955). In this she expressed her continuing optimistic faith in the power of 'rational' social science, internationally pooled, to act as an important tool in support of both democracy and improved social welfare of all peoples.

Alva Myrdal's growing interest in international development strengthened her ongoing commitment to the cause of women as both workers and mothers. Her UNESCO position gave her a vision of how politically effective an international comparative project on these issues could be. Her aim, as in previous work with government commissions, was to 'take stock' of the situation for women in industrialized nations and make the information available to policy makers. She enrolled the collaboration of the British sociologist Viola Klein, author of a critical study of patriarchal attitudes in social sciences, and like herself, also a member of the International Federation of Professional Women. Myrdal used her wide international political and feminist organizational networks to collect a broad array of statistics on women in Sweden, Germany, France, and the USA; and Klein provided the more academic, conceptual summaries and assembled the data into accessible tables and pictograms. The analysis was framed by the fact of women's increased longevity, which left a smaller proportion of a woman's life devoted to childbirth and child rearing and increased women's demands for better educational and employment opportunities. Both authors believed that children needed their mothers for at least the first years of their lives, and with men's domestic contribution still in its infancy, as they saw it, governments and employers needed to support women's fluctuating career trajectories with subsidized high-quality child care, part-time employment opportunities, and antidiscriminatory employment regulations. In the economic boom after the war there was an underlying assumption that the demand for labor would continue to grow, and this was a demand unlikely to be met unless women's participation in the labor market was made easier. Their book, 'Women's Two Roles' (1956) proved a popular success and a much-used textbook in the emerging field of the sociology of women, and it was translated into six languages. But what was seen as controversial in more catholic contexts, was seen by the new, more radical developments in feminism as 'traditionalist' in prioritizing women's responsibility for children over that of men. The dilemmas outlined in the book and its proposals for child care policies and employment regulations to support the woman's right to choose her own life trajectory, remain as relevant today as when they were formulated in what we can now see as a manifesto in need of permanent reaffirmation.

Ambassador for Peace and Security

In 1955 Alva Myrdal left her post at UNESCO to become Sweden's Ambassador to India, Ceylon, Burma, and Nepal. This assignment and her friendship with Prime Minister Jawaharlal Nehru, a strong advocate of universal education and political nonalignment, further deepened her insight into the need for social reform and improved social indicators of the impact of technological development on families and communities. Again she traveled widely, frequently lecturing on the Swedish reform experience, and especially on the role of cooperative and women's organizations. After her return to Sweden in 1961, she continued to work with the Social Democratic Party as a Member of the Swedish Senate, as a Cabinet Minister, and as Ambassador-at-large, – the last a role which led to a new and intellectually and politically all-consuming task, disarmament. As member of the Swedish UN delegation in New York, in 1962 she became Chief Swedish Delegate to the Geneva Disarmament Committee and spent the next decade working with it as representative of nonaligned states; in her own eyes she saw herself as the only woman at the negotiating table representing women across the world, who were faced with living through the consequences of big power politics. The convention led to many minor disarmament

treaties in the area of, for example, test bans, and an improved role for nonaligned states in inspection processes; but the holistic solutions to banning nuclear weapons that she and the nuclear disarmament movement as a whole had hoped for, did not materialize. In the book in which she summarized her experience of the disarmament negotiations, directed at decision makers, independent experts, and concerned citizens in all countries; she did not mince words when she wrote of her increasing feeling of near despair over the behavior of the superpowers indulging in subterfuges and half truths, with their closest dependent allies following suit or keeping silent (1976). Throughout the process, the competitive race between the two superpowers had steady escalated and the militarization of the economy and national life of all almost countries had intensified.

The guiding principle of her criticism was rationality, she argued, and it was the very principle that had been so absent in the deliberations. National security needs had become defined and exaggerated by vested interest, secretiveness, and falsifications of reality. The ordinary public should, she felt, both demand honest accountability of the policy makers and question their underlying ethics. Having painted a bleak future of an escalating arms race, her own call for rationality came to focus around continuing efforts to inform and educate politicians and the public about the powerful lobbies propelling the arms race: the armament industry, scientific and technological interests in weapons performance, and the military notion of balancing and matching as a security measure. More pragmatically, her own agenda for moving forward included less holistic measures, such as the restriction of arms sales, the prohibition of cruel antipersonnel weapons, the demilitarization of ocean space, and the establishment of verification agencies. She emphasized the need for independent action of the great majority of nonaligned states as a means of compelling change, particularly with respect to information gathering about matters relevant to international security to limit the information control exercised by the superpowers and enable the exposure of the lack of honesty in military affairs. The book was an appeal for improved political morality and democratic accountability, reinforced by her own financial support for its wide dissemination.

One of the more important long-term impacts of Alva Myrdal's activities for disarmament and her commitment to information transparency and accountability, was her role in the creation of the Stockholm International Peace Research Institute (SIPRI) in 1966. She became its first Chair. The institute, established to commemorate Sweden's 150 years of unbroken peace, remains one of the more important independent research resources on global security, dedicated to scientific research into the hard facts of war, military expenditure, the arms trade, disarmament and nonproliferation, and to facilitate dialogue by making such data accessible to all interested parties. It cooperates closely with major intergovernmental organizations such as the UN, as well as with scientific and government delegations on a range of issues; and its annual reports are widely used in international contexts. Its annual yearbooks, monographs, and policy papers have become important academic source material for peace and conflict research. But Alva Myrdal's original vision of a world in which sources of insecurity are identified and understood allowing conflicts thereby to be prevented, remains distant. Given the lack of international solidarity and lack of mutual trust among power blocks, the best a disarmament campaigner can hope for, as Alva Myrdal foresaw, continues to be the power of exposure through the use of well-assembled and trustworthy evidence.

In the last decades of her life, alongside her continuing work for the Swedish government on a variety of policy preparatory commissions, including the topics of equality and the relationship between the Church and the State, she held several visiting professorships in the United States and was the recipient of Honorary Doctorates from both American and European Universities. In 1970 she was, jointly with her husband, awarded The West German Peace Prize. She was the first recipient of The Albert Einstein Peace Prize in 1980. In 1982, shortly before her death, she was awarded the Nobel Peace Prize (with Alfonso Garcia Robles, Mexico) for her work for peace and disarmament. With the prize money she supported research on the naval arms race and peace education. She died in Stockholm in 1986 of a brain tumor, having for a period suffered from heart disease and debilitating aphasia.

Alva and Gunnar Myrdal's three children: Jan (Myrdal), b. 1927, Sissela (Bok), b. 1934, and Kaj (Folster), b. 1936, all gained authorial fame; and all three wrote conflicting biographical narratives of life in the Myrdal family. Alva Myrdal's private papers, alongside those of her husband, were left with the Labor Movement Archive in Stockholm; they included their large mutual correspondence, the public availability of which has led to considerable speculation over her private life as a woman and mother, and its relationship to her intellectual and professional activities. Thus her own long and politically active life became as important a legacy in debates about the nature of the relationship between the public and the private, the personal and the political, as her many publications and organizational activities in support of a fairer and safer world.

Abstract

Gunnar Myrdal (1898–1987) is best known for his work in economics and his advocacy of the welfare state in his native Sweden as well as elsewhere. Trained in neoclassical economics, Myrdal later turned to institutional economics. His two most famous works are *An American Dilemma* (1944) and *Asian Drama* (1968). In the former, he presented a sociological analysis of racism in the United States, which was much discussed at the time. And so was *Asian Drama* with its thesis that a progressive and strong state is central to economic development. Together with his wife Alva Myrdal, Gunnar Myrdal helped to shape the Swedish welfare state in important respects.

Gunnar Myrdal (1898–1987), Nobel Laureate in economics, was a passionate advocate of equality, social reforms, and the welfare state. His work as a young economist was inspired by Knut Wicksell and centered around an attempt to introduce expectations into conventional price theory. It was also through his studies in economics that Myrdal became interested in the role of objectivity in the social sciences, a topic to which he was to devote much attention. Myrdal argued that values always influence social science and that the social scientist should state his or her values in a forthright manner. Myrdal became famous in the United States through *An American Dilemma* (1944) and in the rest of the world through *Asian Drama* (1968). The former can be characterized as a sociological analysis of racism in the United States; and Myrdal argued that there exists a conflict in the heart of the average American between the lofty ideals of 'the American way of life' and the tough realities of everyday life. *Asian Drama* lacks a single thesis and represents rather an attempt to weave together a series of themes, including the proposition that a progressive and strong state is central to economic development and to the introduction of equality and freedom in developing countries.

Gunnar Myrdal, social scientist of encyclopedic range, is best known for his two monumental studies *An American Dilemma* (1944) and *Asian Drama* (1968). He was a founding member of the Stockholm School of Economics and one of the architects of the Swedish welfare state. Throughout his life Myrdal was also deeply concerned with the role that values play in the social sciences.

Early Life and Career as an Economist

Karl Gunnar Pettersson – the father later changed the name of the children to 'Myrdal' – was born on 6 December 1898 in Skattungbyn in the province of Dalarna, Sweden. His mother, Anna Sofia Pettersson (born Karlsson), came from a family of farmers and was soft spoken, religious, and bitterly unhappy in her marriage. The father, Carl Adolf Pettersson, also came from a family of farmers but was secular, restless, and upwardly mobile. The father was a building constructor, and in 1904 he moved the family to Stockholm. Myrdal went to a very good high school, Norra Real, and was mainly interested in the natural sciences. He, however, was also deeply influenced by the ideas of the Enlightenment, to which he was introduced by one of his teachers. All through his life he would display a passionate faith in the power of reason.

After having graduated with excellent grades in 1918, Myrdal became a student of law at Stockholm University (*Stockholms Högskola*). The decision to study law had been influenced by his father, but also by Myrdal's own conviction that law would help him better understand how society operates. Whatever conservatism and class prejudices still dominated his mind, and which he had picked up from his family, were soon to be challenged by Alva Reimer (1902–86), whom he met in the summer of 1919 and married in 1924. Like her husband, Alva Myrdal was soon to become a first-rate social scientist and politician; in 1982 she also received the Nobel Peace Prize. While Myrdal had never enjoyed studying law, he quickly took to economics. In 1927 he got his doctorate through a dissertation for which Gustav Cassel had been the advisor, *Prisbildningsproblemet och föränderligheten* (*The Problem of Price Formation and Change*). In this work Myrdal attempted to develop the beginnings of a dynamic theory of price formation by introducing the idea of expectations. In 1930 he published *Vetenskap och politik i nationalekonomien* (*The Political Element in the Development of Economics*), in which he argued that economists often confuse values and facts in their studies, something which endangers both economics as a science and its potential use for social reform. Based on an article from 1932, Myrdal published a book-length study in 1939 entitled *Monetary Equilibrium*. In this work he attempted to further develop Knut Wicksell's theory of monetary equilibrium by introducing the notion of expectations. In the early 1930s Myrdal also produced a couple of writings for the Swedish Social Democratic government in which he advocated an underbalanced budget as a way of countering a downturn in the business cycle. These works were based on Myrdal's discussions with his friend Erik Lindahl and the Swedish Finance Minister Ernst Wigforss.

All of these writings, except for *Vetenskap och Politik*, are regarded today as important contributions to the Stockholm School of Economics, which is usually defined as a Keynesian type of economics, based, however, on Knut Wicksell's ideas. The value of these works is today mainly historic. They nonetheless played a crucial role in the development of Myrdal's

ideas, especially in his attempt to construct a dynamic theory of causation, based on Wicksell's ideas. *Vetenskap och Politik*, on the other hand, has aged rather well and represents a still valuable contribution to the history of economic ideas. While Myrdal would always approvingly refer to its main thesis – that neoclassical economics is deeply biased through its origin in the natural law tradition and in utilitarian philosophy – he would later criticize his youthful assumption that it was possible to separate out a core of economics that was free from all values.

Political Activities and an American Dilemma

Both Gunnar and Alva Myrdal decided in the early 1930s to become actively involved in politics and were to play a crucial role in the construction of the Swedish welfare state through their advocacy of 'social engineering.' The timing to do so was perfect, since in 1932 the Social Democratic Party had won the election and was eager to transform the poor and class-ridden Sweden into a real 'people's home' (*folkhem*). Gunnar Myrdal not only helped to formulate the economic aspects of the new policy that now came into being, but also its social policy. This he did, in close collaboration with Alva Myrdal, through an avalanche of writings as well as his participation in various royal commissions, appointed by the government to investigate some specific issue. The basic message of the two Myrdals was that social policy had to be fundamentally changed, from focusing on symptoms, to becoming 'prophylactic.'

Gunnar and Alva Myrdal presented their vision for what a new and modern Sweden would look like in *Kris i befolknigsfrågan* (*Crisis in the Population Question*, 1934), which became a political best seller. 'All of society,' they here argued, would have to be changed, so that 'the quality of people' could be improved and better adjusted to the demands of modern, industrial society: living standards, consumption patterns, the way children are brought up, the structure of education, and much, much more. Though permeated by the authors' generosity and enlightenment, *Kris i befolkningsfrågan* also evinces an enormous belief in the authority of science and experts. The Myrdals' advocacy of sterilization of certain categories of people, who were deemed unfit for the new society, has also been criticized.

By the mid-1930s, Myrdal's work had become so dominated by practical and political concerns that he longed for a return to academic studies; and when he was asked in 1937 by the Carnegie Corporation if he would lead a study on the blacks in the United States, he accepted. During the next few years, Myrdal traveled around in the United States like a latter-day Tocqueville, interviewing people from all strata – 'I am from Sweden and I do not know anything about the race problem. What can you tell me?' Through the backing of the Carnegie Corporation, Myrdal put together a small circle of collaborators, and he also engaged, in one way or another, some 70 other scholars, including Samuel Stouffer, Louis Wirth, and E. Franklin Frazier. Fearing many times that he would never be able to synthesize the enormous amount of material that he had commissioned in 1944 Myrdal had the satisfaction of seeing *An American Dilemma* appear in print in two volumes of more than 1400 pages.

Myrdal's work was much commented upon, and most of what was said was positive. *An American Dilemma* was actually to dominate the discussion of ethnicity in the United States from the end of World War II till the 1960s, and it also played an important role in the decision of the Supreme Court in 1954 to declare segregated schools unlawful (*Brown vs Board of Education*). From the mid-1960s till the 1970s, Myrdal's book was criticized for depicting certain aspects of black life as pathological and also for not advocating change from the bottom up; and today, *An American Dilemma* is seen primarily as being of historical interest in ethnic studies.

Myrdal's basic thesis – that there is a moral dilemma in the heart of the average person between 'the American Creed' and everyday behavior toward blacks – may seem old-fashioned and passé today. This, however, should not prevent one from realizing the value of other parts of *An American Dilemma*, especially its appendices on values and on cumulative change (Appendices 1–3). In the first two of these appendices, Myrdal argues that social scientists should always state their value premises since these deeply influence the analysis. In Appendix 3 Myrdal presents the core of his own social science approach that is centered around Wicksell's theory of unstable equilibria or what Myrdal calls 'the principle of cumulation.' An initial change, Myrdal explains, can set off further changes; and these may then move the whole system either in an upward direction or in a downward direction ('vicious circles').

Activities After World War II and Becoming an Institutionalist

After *An American Dilemma* Myrdal returned to a combination of politics and applied research till the mid-1950s, serving first as Minister of Trade in Sweden (1945–47) and then as Executive Secretary in the Economic Commission for Europe of the United Nations (1947–57). Neither of these two experiences were particularly successful for Myrdal, who was more of an intellectual than a politician; and he soon longed to return to academic studies. The topic that he chose to focus on this time was underdevelopment, and a fine introduction to his early efforts in this direction can be found in *Rich Lands and Poor* (1957). It is in this work, for example, that Myrdal introduces the idea that a strong economic development in one area may either impede or accelerate economic growth in nearby areas ('backwash effects' and 'spread effects'). His most sustained effort to understand underdevelopment, however, took 10 years to produce and appeared in 1968 in three volumes of more than 2000 pages: *Asian Drama*.

Like *An American Dilemma*, *Asian Drama* has been much debated. The initial reaction was many times positive, but today Myrdal's work is less often referred to. One reason for this is the fact that his strong advocacy of large-scale state planning and state intervention as well as his clear stance for what he calls 'The Modernization Ideals' do not go very well with today's emphasis on market forces and the prevalent skepticism toward Western ideals. Still, several parts of *Asian Drama* are still of interest, such as the notion of 'the soft state,' the critique of various aspects of neoclassical economics, and Myrdal's attempt to use Wicksell's theory of cumulative causation to

construct a theory of institutionalist economics (see especially Appendices 1–3).

After *Asian Drama* Myrdal kept writing books and articles, and he also gave lectures all over the world. In 1969 he published a small and still useful volume entitled *Objectivity in Social Research*, and in 1974 he was awarded the Nobel Prize in Economics, together with Friedrich von Hayek. Autobiographical elements can be found in *Against the Stream* (1973) as well as in *Hur styrs landet?* (*How is the Country Governed?* 1982). His reference to the superiority of institutionalist economics over neoclassical economics became ever stronger; and the essay *Institutional Economics* (1978) is especially recommended. An attempt to write a sequence to *An American Dilemma*, entitled *An American Dilemma Revisited*, had, however, to be called off in 1985, due to illness. Gunnar Myrdal died on 17 May 1987 in Stockholm. To his very last day he remained a firm believer in the ideals that he shared so strongly with his beloved wife Alva Myrdal, and which for him were symbolized by the one word with which *An American Dilemma* ends: *Enlightenment*.

Mysticism

Dan Merkur, University of Toronto, Toronto, ON, Canada

This article is reproduced from the previous edition, volume 15, pp. 10270–10273, © 2001, Elsevier Ltd.

Abstract

Mysticism consists of a practice of religious ecstasies, together with ideologies, ethics, rites, myths, legends, magics, etc., related to the ecstasies. Mysticism is institutionalized in 90 percent of human societies. Mysticism occurs not only in scripture-based religions, but also in oral religious traditions, where it is known as shamanism, vision quests, spirit possession, spirit mediumship, and prophetism. In oral religions, mystics often assume leadership positions as intermediaries between the numina and the social group. Because book religions invest authority in scriptural exegetes, mystics are marginalized and typically seek politically innocuous ecstasies. In other cases, mystics aspire to authority and become would-be prophets. The contents of mystical experiences may be subdivided into narrative and unitive ecstasies. Both occur in states both of trance and of reverie. Trances reify imaginations as hallucinations and delusions, whose uncritical validation devalues perceptible reality and promotes dissociative philosophies and behavior. Reveries are instead self-evident as heurisms. Mystics have traditionally sought metaphysical transformations, but positive psychological growth has been demonstrated in a few cases.

Definition of Mysticism

Mysticism consists of a practice of religious ecstasies, i.e., of religious experiences during alternate states of consciousness, together with whatever ideologies, ethics, rites, myths, legends, magics, etc., are related to the ecstasies. 'Ecstasy' may be defined as any experience of involuntary belief in the reality of the numinous, i.e., of the holy or demonic. Whenever the numinous is as manifestly real as perceptible reality is during waking sobriety, consciousness has been sufficiently altered that the experience is intrinsically religious (Merkur, 1992).

Since the paradigm shift promoted by the work of Katz (1978, 1983), mysticism is no longer defined as the ideology and practices surrounding the experience of union with the Absolute (Underhill, 1910), or ultimate reality, etc. There is abundant evidence that the people who traditionally have been called mystics have enjoyed many varieties of religious ecstasies. Comparative studies of mysticism currently include the vision quests and shamanism, spirit possessions and spirit mediumship, prophetism and seers, etc., of the oral religious traditions, as well as the visions, voices, mystical unions, enthusiasms, etc., of the scripture-based religions.

Mystical experiences are as varied as the dreams of sleep. Not only personal matters, but also culturally and historically variable religious ideologies contribute to the contents of mystical experiences and their postexperiential interpretations. People in all cultures may potentially experience all possible varieties of religious experience. The world's ecstatic religious traditions each tends to accommodate a considerable diversity of ecstatic experiences, even when certain types are privileged. Conformity is required in matters of doctrine and behavior much more than in experience. The vagueness or nonspecificity of many traditional doctrines permits them to be applied simultaneously to diverse religious experiences.

No sociological research has yet been done that conforms with mysticism's current definition. Collating existing research on shamanism, spirit mediumship, prophetism, mysticism in the book religions, etc., in search of common denominators, discloses few commonalities. People who make religious uses of alternate states of consciousness take their religion more personally and seriously than the general population. They tend to be convinced, and not only hopeful, about the reality of their objects of belief. Religion is not only a social institution for them; it is an integral component of the cosmos. In Allport's (1959) terms, their religiosity is 'intrinsic,' and not only 'extrinsic.'

In other respects, mystics are diverse. Some mystics are religiously and/or socially conservative, but others are revolutionary. Some seek to transcend all perceptible phenomena; others address the immanence of spiritual phenomena within material reality. Some shun their bodies and engage in asceticism. Others celebrate both their bodies and the physical world. Some seek to withdraw from society, but others participate within it. Some mystics prioritize a single type of mystical union, e.g., nothingness, or all-being, or identity with God; but others favor complex systems of multiple types of religious ecstasy that include both visions and unions.

The term 'mysticism' derives historically from the noun *mystes*, 'mystic,' meaning the possessor of a secret, and denoting an initiate of a classical Greek or Hellenistic Mystery. The Mysteries were rites of initiation that induced religious experiences. Technical terms of the Mysteries were taken over by Plato, Philo, and the Christian Church Fathers, who applied the terms to their own practices of religious experiences. By the early medieval period, Christianity officially denied possessing any secrets that had not been publicly divulged through Christ. Hindu yoga, Buddhist *vipassana* meditation, and Confucian meditation, among other mystical traditions, similarly teach their alternate-state practices openly. At the opposite extreme, Taoism, Hindu and Buddhist tantra, theosophical Sufism, the Kabbalah, and Western alchemy are so very secretive that they encode their teachings in secret languages, whose meanings cannot be understood by noninitiates.

Incidence and Varieties of Mystics

In a survey of 488 societies worldwide, Bourguignon (1973) found that 90 percent had institutionalized one or another

religious use of alternate states of consciousness. In different surveys in Western cultures, between one-third and one-half of the population has been found to have had one or more mystical experiences (Greeley, 1975). A considerably smaller part of the population pursues mystical experiences on a frequent or habitual basis. Many factors have contributed to the distinctive historical forms that different mystical traditions have taken.

Shamans

A shaman may be defined as a religious functionary who enters ecstasy and, by commanding the aid of helping spirits, intermediates between the social group and the numina (Hultkrantz, 1973). Shamanism has its origin and major distribution in hunter cultures. Like hunters, shamans' ecstasies are highly mobile. In their visions, shamans may travel out of their bodies to the sky, netherworld, or distant overland locations. Shamans also summon helping spirits to them, sometimes from considerable distances, and they send them abroad on distant errands. Shamans relate to their helping spirits much as hunters relate to half-wild dogs.

A shaman typically is paid for services rendered to a client, such as healing. In their ecstasies, shamans may also find game animals, placate angry deities, guide new ghosts to the afterlife realm, and hex enemies in war. In some hunter cultures, vision quests are pursued more generally by part or all of the society. In these cases of 'democratized shamanism,' shamanism occurs as a private practice, and only mystics who are exceptionally gifted emerge as professionals.

Shamanism persists in agricultural communities in varied forms. Democratized shamanism persisted as a practice among warriors in Indo-European cultures (e.g., Glosecki, 1989). It was also adapted to group possession states in the classical Mysteries of Dionysus. In late antique and medieval Europe, shamans who lacked traditional social locations within their communities emerged as itinerant seers (Brown, 1981; Davidson, 1989), magicians (Smith, 1978), and witches (Ginzburg, 1983). Where seers have a clientele, magicians and witches often engage in shaman-like conjuring of spirits, but privately rather than professionally.

Spirit Mediums

A spirit medium may be defined as a religious functionary who enters ecstasy and, through states of possession, serves as a vehicle for the manifestation of a numen to the social group. Spirit mediumship has its major distribution in clan-based farming villages, both in Africa (Walker, 1972) and in Southeast and East Asia (Elliott, 1955; Paper, 1995). The sedentary life style of farming villages is reflected in the lodging of spirits within mediums. Mediums and their spirits perform no errands that require travel outside the village. Much spirit mediumship is intimately connected with the worship of ancestral ghosts. Deference to family elders, which is economically motivated by the ownership and inheritance of arable land, is continued after the elders' deaths through the agency of mediums, whom the ancestral ghosts possess. The deference is reflected, among other manners, in mediums' claims that all of their activities while possessed are performed by the possessing spirits, while they themselves are passive.

Spirit mediums may also be possessed by gods and spirits that are not ancestral ghosts. Spirit mediumship also occurs in democratized forms, where large numbers of people within a social group engage communally in possession states, and only a few show sufficient virtuosity to function as professionals. Spirit mediumship and possession may persist into more complex societies, e.g., in the theurgy of late antique Hellenism (Luck, 1989), enthusiasm in Protestant Christianity (Knox, 1950), and modern New Age channeling.

Prophets

A prophet may be defined as a religious functionary who enters ecstasy, learns of the will of the god, and later communicates the divine will to the social group. Prophets have their major distribution in kingdoms, whose gods are imagined as kings, and whose prophets are imagined as heralds, spokespeople, or ambassadors of the gods (Cross, 1973). Prophetism had its origin and classical location in urban societies with differentiated labor and trades, both in the ancient Near East and East Asia. Prophetism can be conceptualized as an adaptation of ecstasy to monarchic politics, with the prophet's god outranking the king. Prophets' ecstasies favor verbal revelations from their gods, but may include shamanic and mediumistic forms that have been adapted to monarchic politics.

Anthropologists also use the term 'prophet' in reference to shamans and spirit mediums who have been influenced by missionaries' accounts of Biblical prophets and developed hybrid types of mysticism that reflect their postcontact situations.

Mystics in Scripture-Based Religions

Because book religions invest religious authority in scriptures and their official interpreters, they marginalize professional ecstatics. Mysticism is then often pursued by a leisure class, which may embrace poverty in order to support its practices, as among Hindu forest dwellers, and in Buddhist and Christian monasticism. In other cases, e.g., Taoism, Sufism, and Kabbalah, mysticism has been pursued by individuals sufficiently affluent to devote leisure time to it.

Mystics in the book religions often avoid conflict with religious authorities by favoring varieties of ecstatic experience that are socially and political powerless. Unitive experiences, which are not useful for professional ecstatics, may consequently be privileged. However, other ecstasies are often pursued as well.

Mystics in the book religions may be public religious functionaries, e.g., as leaders or teachers of other mystics. Their leadership roles among nonmystics tend to be limited to religious revival movements, in which mystics proselytize ecstasy among their co-religionists.

Although most mystics are sociopolitically conservative, a minority are radical and potentially revolutionary. In such cases, mystics in the book religions typically seek social roles appropriate to prophets. Rather than seeking ecstasies that are accommodating, inconspicuous, and innocuous, they seek inspirations that claim authority to transform their religions and/or societies. The would-be prophets may then

emerge as charismatic founders of sects, schisms, and/or cults. An apocalyptist may be conceptualized as a would-be prophet in a book religion, who seeks the radical reformation of society, often as an aftermath of catastrophe and revolution. Apocalyptists may found or belong to millennial movements.

The Contents of Mystical Experiences

All ideas and practices that may be entertained and performed during normal waking sobriety can also be thought and done during at least many varieties of ecstasy. Ecstasies facilitate unconscious manifestations that tend not to occur otherwise; but they do not necessarily preclude the activities of normal consciousness. Mysticism may embrace the whole of non-ecstatic religiosity, together with an additional component i.e. contributed by the ecstatic experiences.

Ecstasies may be subdivided on psychological criteria into two major categories. Some ecstasies involve narratives, as do daydreams and night dreams. The narratives may consist of visual images, with characters, sceneries, dialogue, etc. They may instead consist exclusively of words. Narrative ecstasies can also have physical dimensions and take form as automatic speech, automatic writing, automatic dramatization (i.e., possession), and other types of behavior. Somatizations (stigmata) may also occur.

The second category of ecstasies may be termed unitive experiences. All unitive ecstasies involve a sense of separate things becoming unified. What is unified varies. In normal waking sobriety, our sense of self is elastic. Our senses of our 'selves' is limited to our bodies when naked; extends to clothing when dressed; and may include, e.g., even the fenders of a vehicle when we are driving. Romantic partners, children, family, ethnic group, and nation may also be included in the normal fluctuation of the sense of self. Unitive ecstasies include exceptional instances of the elasticity of the self. In some instances of mystical union, the self is co-extensive with the entire physical cosmos; in others, with infinite timeless being; in others again, with God; in still others, with ultimate nothingness. Other commonly encountered unitive ecstacies include a sense of identity with some one particular thing in the cosmos.

Unitive experiences are always unconsciously dyadic. Just as self exists and is defined psychologically only in relation to others, so mystical unity exists and is defined experientially only in relation to the absolutely Transcendent. One cannot experience self as transcendent, unless the ideas of the self and the Transcendent have been brought to union. Conversely, experiences of self and a numinous being in a manifestly dyadic relationship may be categorized as unitive experiences. Self and other are united in a unifying relationship during experiences of the immediate presence of a numinous power, or absolution by a numinous power, etc.

So-called paranormal phenomena, such as precognition, clairvoyance, and meaningful coincidences ('miracles') are further varieties of unitive experience. They unite subjective fantasy with the objectivity of perceptible reality, imparting objective reality to imagined ('extra-sensory') perceptions (Merkur, 1998, 1999).

The Varieties of Alternate States

Most mystical experiences occur during states of trance. Religious trances are instances of either self-hypnosis or hetero-hypnosis. In other cases, mysticism depends on trances that occur as symptoms of hysteria, epilepsy, and other pathologies. In all cases, suggestion – either autosuggestion or hetero-suggestion – is responsible for directing the trance to serve religious purposes (Arbman, 1963).

An important aspect of the trance state is its ability to reify the contents of consciousness (Shor, 1959). For example, a trance state is all that is necessary in order to transform a visual daydream into a waking hallucination. Instead of seeming to be imaginary, daydream images may seem during trance to be objectively existing, external realities. Trance states may similarly transform speculative ideas into delusions that have the force of firm convictions.

Trances are often termed 'dissociative states' because the reification of fantasies leads to a corresponding devaluation and/or denial of sense perceptions. Mystics who use trances uncritically may develop dissociative religious doctrines that reject the perceptible world in favor of transcendent realms or states, otherworldliness, asceticism, devaluation of mortal life, community, and the physical world, and asocial or anti-social behavior (Furst et al., 1976). Mystics may, however, use trance states critically, much as hypnotherapists do.

Some mystical experiences occur in a different class of alternate states that may be termed 'reveries.' Nonecstatic forms of reverie include daydreams, creativity, and hypnagogic states between waking and sleeping. Reveries of ecstatic intensity include 'peak experiences,' which typically occur spontaneously and last only a few seconds or minutes. Sensory deprivation is a means to induce reverie states that may reach ecstatic intensity. Psychedelic drugs, i.e., psilocybin, mescaline, LSD, and THC, the active factor in marijuana, similarly induce reverie states, as distinct from trances (Merkur, 1993).

Both narrative and unitive ecstasies may occur in either trances or reveries. Reveries differ from trances, among other manners, in the ecstatic's knowledge during reverie that his or her experiences are subjective and intrapsychic, rather than objective and external. They are self-evident as heuristic phenomena. Religious reveries seem subjectively to be apperceptions of truth through the medium of imagination. The experiences take form as pseudo-hallucinations and illusions, where the same narrative and unitive experiences have the force of hallucinations and delusions when they occur during trances.

Psychological Transformation

Mystics traditionally have sought transformations that were metaphysical in nature: magical empowerment, salvific perfections of their souls, etc. Since the 1970s, transpersonal psychologists have argued that mystical transformations have powerful psychological benefits, consistent with Maslow's (1964) concept of 'self-actualization.' Some mystical practices have been shown to be beneficial developmentally (Sacks, 1979; Emavardhana and Tori, 1997), but others may be harmful.

Myth in Religion

Robert Segal, University of Aberdeen, Aberdeen, UK

Abstract

Modern theories of myth, most of which hail from the social sciences, can be classified into two main categories. In the nineteenth century theorists saw myth as the 'primitive,' outdated counterpart to science, which was considered largely modern. It was assumed that myth arose and functioned to explain the physical world. The personalistic, religious explanation was incompatible with the impersonal explanation given by science. One could not consistently have both myth and science. In the twentieth century theorists saw religion as almost anything but the primitive counterpart to science. Either myth was no longer assumed to be about the physical world, or myth was no longer assumed to serve to explain the physical world, or both. Myth now diverged from science and was therefore compatible with it. Myth was no longer automatically tied to religion. In the twentieth-first century the question is whether myth can be brought back to the physical world as an explanation of it, yet in a way compatible with science.

Myth

There is no uniform definition of myth. For some theories of myth, myth need not even take the form of a story, as might be assumed, but can instead be a belief or a conviction. For other theories, mythological stories need not take place in the past but can take place in the present or the future. Myths can take place on earth, in heaven, or in space. The characters in myth need not be gods but can alternatively be humans or even animals. What happens in myth is open-ended. Myth need not, for example, be about the creation of something but can instead be about the destruction of something or be about an event within an existing family, society, or cosmos.

There are many kinds of myths – among them creation myths, myths of paradise, flood myths, myths of nations and of races, and myths of the future. There is diversity even within each kind. For example, in hero myths, heroes are most often human, yet they can also be divine. Animals, especially ones called tricksters, can be heroic as well. Heroes can be ordinary as well as extraordinary persons. Sometimes anyone can be a hero, which is not to say that anyone automatically is a hero. There can be child heroes as well as adult heroes. Heroes can come from any class. And heroes can come from either gender. Finally, some theories of myth classify stories of heroes as legends rather than as myths proper.

Theories of Myth

A myth can be studied either by itself, in isolation from other myths, or in comparison with other myths. Theories of myth compare myths with one another, indeed with all others. Theories are generalizations about myth. They provide answers to the main questions about any myth: What is its origin? What is its function? What is its subject matter? The answer is the same for every myth.

The question of origin asks why and how myth arises. The origin proposed by a theory is recurrent rather than historical. The origin refers not to the time and place of the first appearance of myth, such as the Garden of Eden, but to why and how myth arises whenever and wherever it does. The answer to the 'why' of origin is not a location but a need, which antedates myth and which myth is created to fulfill. What the need is, varies from theory to theory. It can range from the brute need for food to the sublime need for meaningfulness in life.

The 'how' of origin refers to the means by which myth arises. For example, a theory may contend that even with the need for hunger, a myth will not arise without a group. Or a theory may contend that even with a need for explanation of the physical world, a myth will not arise unless there exists the belief in god. Some theories ignore the how of origin.

The question of the function of myth addresses why and how myth lasts. Like the origin, the function is recurrent. The why of the function is the flip side of the why of the origin: whatever need explains the creation of myth also explains the continuation of myth. The how is the means by which myth lasts. For example, a theory may assert that myth lasts only as long as it is tied to a ritual or to a group.

The subject matter of myth refers to the content. The key issue is whether myth is to be read literally or symbolically, and theories vary in their views. If myth is to be read symbolically, what is being symbolized?

Most theories of myth come from the social sciences – from anthropology, sociology, psychology, political science, or economics. Social scientific theories tend to focus on the origin and function of myth. It is not that social scientists confine themselves to behavior and ignore texts. It is that they tend to emphasize why and how texts are created and read (or heard) and not what texts say. In one sense of an admittedly confusing pair of terms, the social scientific focus is on the *explanation* rather than the *interpretation* of myth (see Segal, 1992).

By contrast, theories of myth from the humanities – art, literature, philosophy, and religious studies – focus on the content, or the *interpretation*, of myth. What is myth saying? is the key issue. What are the themes or patterns in myth? Must myth be a story?

Some theorists seek both to explain and to interpret myth. For example, Sigmund Freud and C.G. Jung not only identify who creates and uses myth and why but also offer full glossaries for reading myth, which means for translating the literal meaning into a psychological one. E.B. Tylor insists on a literal

 http://dx.doi.org/10.1016/B978-0-08-097086-8.84023-4

interpretation of myth to match his view of the origin and function of myth. By contrast, Rudolf Bultmann, Hans Jonas, and Albert Camus confine themselves to the content, for which one might use the somewhat confusing synonym "meaning". They translate myth into existentialist terms and just do not consider why myths are created and perpetuated.

In addition to the questions of the origin, the function, and the subject matter of myth, there is also the question of the truth of myth. Theories can judge myths as true or false or take no stand. Tylor takes myth to be false literally and stops there, refusing to consider it symbolically. Eliade takes myth to be true literally. Bultmann, Jonas, Freud, Jung, and Camus take myth to be false literally but true symbolically.

In popular parlance myth is a false belief and a belief taken literally, whether or not the belief is in the form of a story. Books with titles like 'President X: The Man and the Myth,' pit myth against truth. But myth taken as mere myth misses the point. Myth has a grip that goes far beyond its factual status. To label a belief a myth is to elevate, not denigrate, it by noting the hold that it has on those who accept it, no matter what the evidence. A myth is not the false belief that I have ten dollars in my pocket. It is the conviction, hard to dislodge, that President X was courageous, heroic, selfless, or saintly. At the same time a myth need not be false – contrary to phrases like 'the man and the myth.' A myth can equally be true. The power that myth possesses transcends its truth as much as its falsity. When true, myth is not just a true belief but a resolutely held true belief.

Theories of myth are hardly a modern invention. They go all the way back to the pre-Socratics (see Chase, 1949: Chapter 1; de Vries, 1961: Chapter 1). Only in the last century and a half, however, have theories become scientific, for only since then have there existed the social sciences. Some social scientific theories may have counterparts in earlier ones (see Feldman and Richardson, 1972), but earlier theorizing was largely speculative and philosophical. Modern theorizing is far more empirical and testable. Even modern theories from literature, religious studies, and philosophy reflect the influence of the social sciences.

The most straightforward way to compare theories of myth is by discipline. But the differences among disciplines are often blurry. For example, the theories of Tylor, Bronislaw Malinowski, and Claude Lévi-Strauss are as much psychological as anthropological. It is more telling to compare theories by the questions they ask and by the answers they give.

Myth as the 'Primitive' Counterpart to Science

An apt starting point is the theories of Tylor (1832–1917), the pioneering English anthropologist, and of J.G. Frazer (1854–1941), the pioneering Scottish classicist and anthropologist. They epitomize what can be called the nineteenth – century view of myth. For Tylor (1871), myth originates and functions to explain physical events. For Frazer (1911–15), myth originates and functions not only to explain but also to control physical events, such as rainfall. For both, myth is not itself science, even of a 'primitive' variety, which is the position of Lévi-Strauss (1908–2009), the French anthropologist. Rather, myth is the 'primitive' *counterpart* to science, which is exclusively modern. 'Modern myth' and 'primitive science' are contradictions in terms.

By science, Tylor and Frazer mean natural, not social, science. The events explained by myth are primarily those in the external world, such as the rising and setting of the sun, though also explained are biological events, such as birth and death. For Tylor, the payoff of myth is wholly intellectual: "Man's craving to know the causes at work in each event he witnesses … is no product of high civilization, but a characteristic of his race down to its lowest stages" (Tylor, 1871: Volume I, pp. 368–369). For Frazer, the payoff is practical – above all that of getting food by getting crops to grow.

For both Tylor and Frazer, myth and science alike originate through observation, inference, and generalization. Both cover the same range of phenomena. There is nothing in the physical world that myth cannot explain but that science can, or vice versa. Both myth and science are meant literally, though the inconsistent Frazer alternatively reads myth symbolically. The difference between myth and science is in the explanations themselves. Myth, a part of religion, attributes events to the decisions of gods. Science attributes events to impersonal processes.

Myth and science duplicate each other in function but exclude each other in content. Myth and science are not like horses and cars. Once cars were invented, one could still use horses. By contrast, once science arose, which as the commonplace explanation of physical events goes back only a few hundred years, one could no longer use myth. The explanations given by both are mutually exclusive, for both are direct. In myth, gods act in place of scientific laws, not behind them, even if myth in fact presupposes physics to explain how a god creates rainfall, for example. While myth is as rational as science, it is false.

In the twentieth century Tylor's and Frazer's theories were spurned on many grounds: for setting myth against science and thereby precluding modern myths; for subsuming myth under religion and thereby precluding secular myths; for deeming the function of myth explanatory; for deeming myth false; and (half the time for Frazer) for reading myth literally. Postmodernism would dismiss myth as explanation and would treat myth as sheer story. Nevertheless, Tylor's and Frazer's theories remain central to the study of myth, and all other theories can be seen as rejoinders to them.

One response to Tylor and Frazer has been to take the function of myth as other than explanatory, in which case myth diverges from science and can therefore coexist with it. Another response to Tylor and Frazer has been to read myth other than literally, in which case myth does not even refer to the physical world and can therefore likewise coexist with science. The most radical response to Tylor and Frazer has been to alter both the explanatory function and the literal reading of myth.

Myth as More or Other than Explanatory in Function

The most influential reinterpreters of the function of myth have been Malinowski, Lévi-Strauss, and Eliade. It is not clear whether for Malinowski (1884–1942), the Polish-born anthropologist, moderns as well as 'primitives' have myth. It is clear that for him 'primitives' have science as well as myth, so that myth cannot be the primitive counterpart to modern science. For Malinowski, myth is no more the equivalent of applied science – Frazer's view – than the equivalent of

theoretical science – Tylor's view. Primitive peoples use science to explain and, more, to control the physical world. They use myth to reconcile themselves to aspects of the world that cannot be controlled.

Myth reconciles humans to the travails of life by rooting those travails in the primordial actions of gods or humans. Humans age because a god or human once did something that brought old age irremediably into the world: "The longed-for power of eternal youth and the faculty of rejuvenation which gives immunity from decay and age, have been lost by a small accident which it would have been in the power of a child and a woman to prevent" (Malinowski, 1926: p. 104). Myth pronounces the world not the best possible one but, in the wake of irreversible events, the only possible one. Still, the world becomes less capricious than it would otherwise be. In tracing back the origin of phenomena, myth does explain those phenomena, but as a means to an end rather than, as for Tylor, the end itself.

For Tylor and Frazer, myth deals with physical phenomena. For Malinowski, it deals equally with social phenomena like customs and laws. Myth still functions to reconcile humans to the unpleasantries of life, but now to unpleasantries that can be cast off by members of society. Myth spurs members to accept the impositions of society by conferring on them the clout of tradition. In the case of physical phenomena the beneficiary of myth is the individual. In the case of social phenomena it is society itself. If moderns do not have myths, their counterpart is ideology.

The most influential contemporary theorist of myth, the French anthropologist Claude Lévi-Strauss, at first glance seems a throwback to Tylor. For Lévi-Strauss, myth is an exclusively primitive enterprise yet a rigorously intellectual one. He denounces nonintellectualists like Malinowski as vigorously as Malinowski denounces intellectualists like Tylor and would doubtless denounce Levi-Strauss. Indeed, in declaring that primitive peoples, "moved by a need or a desire to understand the world around them, … proceed by intellectual means, exactly as a philosopher, or even to some extent a scientist, can and would do" (Lévi-Strauss, 1978: p. 16), Lévi-Strauss seems indistinguishable from Tylor. But Levi-Strauss in fact argues that primitive peoples think differently from moderns rather than, as for Tylor, think less rigorously than moderns.

Primitive, or mythic, thinking is concrete. Modern thinking is abstract. Primitive thinking focuses on the observable, sensory, qualitative aspects of phenomena rather than, like modern thinking, on the unobservable, nonsensory, quantitative aspects. Yet myth for Lévi-Strauss is no less scientific than modern science. It is simply part of the 'science of the concrete' rather than part of the science of the abstract, to which it is less at odds than askew myth is primitive science, but it is not inferior science.

Myth is an instance of thinking per se for both primitives and moderns because it classifies phenomena. According to Lévi-Strauss, all humans think in the form of classifications, specifically pairs of oppositions, and project them onto the world. Many cultural phenomena express oppositions. Myth is distinctive in tempering oppositions: "the purpose of myth is to provide a logical model capable of overcoming a contradiction" (Lévi-Strauss, 1958: p. 105). Myth resolves a contradiction either by providing a mediating or analogous middle term or by providing an analogous contradiction. Either tactic narrows and thereby alleviates the contradiction, but neither fully resolves it.

Like the contradictions expressed in other phenomena, those expressed in myth are apparently reducible to the fundamental contradiction between 'nature' and 'culture.' Humans experience themselves as at once animal-like and civilized. This split stems from the projection onto the world of the oppositional character of the mind. By diminishing that opposition, myth makes life more bearable and tempers a logical conundrum the payoff is intellectual. It is like that from solving a mathematical puzzle.

In calling his interpretation of myth 'structuralist,' Lévi-Strauss distinguishes it from 'narrative' interpretations, which adhere to the plot of myth. Lévi-Strauss dispenses with the plot and locates the meaning of myth in the structure. The plot is that element – say, event – a leads to event B, which leads to event C. The structure, which is identical with the expression and diminution of contradictions, is either that events A and B constitute an opposition mediated by event C or that events A and B are as opposed to each other as events C and D, an analogous opposition, are opposed.

Lévi-Strauss confines himself to primitive myths, but other structuralists analyze modern myths. In *Mythologies* (1972) the French semiotician Roland Barthes (1915–80) takes as myths various cultural artifacts and shows how they serve to justify the bourgeois outlook of postwar France. The function of myth here is not intellectual but ideological. Myth has nothing to do with natural science.

Where Lévi-Strauss largely analyzes myths independent of their social context – the grand exception is his analysis of the myth of Asdiwal – others, inspired by him have tied myths to their contexts. The most prominent have been the French classicists inspired by not only Lévi-Strauss but also the classicist Louis Gernet, after whom they are called the Gernet School. For these classicists – Jean-Pierre Vernant (1983), Marcel Detienne (1977), Pierre Vidal-Naquet, and Nicole Loraux – the relationship between myth and society is much more malleable and ironic than it is for Malinowski or even Barthes. Myth can as readily challenge as bolster existing ideology.

Unlike Malinowski, the Romanian-born historian of religions Mircea Eliade (1907–86) has no hesitation in making one function of myth explanatory. For him, as for Tylor, myth attributes events to the decisions of gods. Like Malinowski, Eliade includes social phenomena as well as physical ones. Explanation for Eliade is both an end in itself and a means to another end, which is magically to return to the time of the myth, the time of the origin of whatever phenomenon it explains. In this 'primordial time' gods are nearest to humans, as in the biblical case of "the Lord God['s] walking in the garden of the cool of the day" (Genesis 3:8). The return to primordial time reverses the everyday separation from gods, a separation that is equivalent to the fall, and is regenerative spiritually: "What is involved is, in short, a return to the original time, the therapeutic purpose of which is to begin life once again, a symbolic rebirth" (Eliade, 1968: p. 8). The ultimate benefit of myth is proximity to gods, one or more.

Eliade ventures beyond the other respondents to Tylor in proclaiming myth panhuman rather than merely primitive. Where for Malinowski science, but presumably not myth, is

universal, for Eliade myth but not science is. He cites modern novels, plays, and films with the mythic theme of yearning to escape from the everyday world into another, earlier one. If even professedly atheistic moderns thus have myths, then myth must be universal. The only difference between 'primitive,' or 'archaic,' peoples and moderns is that moderns do not know that they have myth.

How modern myths, which do not involve gods, provide entree to gods, Eliade never discloses. How the explanations given by modern myths, which are entirely about social phenomena like customs, inventions, and nations, are compatible with the explanations given by the social sciences, Eliade never discloses either. For him, the fact that moderns have both myth and science, social or natural, is proof that they are compatible. By contrast, Tylor and Frazer would argue that any preservation of traditional myths in the wake of science attests to sheer human inconsistency rather than to any lingering yearning for myth.

Myth as Other Than Literal in Meaning

The most prominent reinterpreters of not the function but the meaning of myth have been the German New Testament scholar Rudolf Bultmann (1884–1976) and the German-born philosopher Hans Jonas (1903–93). Both were students of the early Martin Heidegger and offer existentialist readings of myth. While they limit themselves to their specialties, Christianity and Gnosticism, they presuppose a theory of myth per se.

Bultmann acknowledges that, read literally, myth is about the physical world and is incompatible with science. But unlike Malinowski and Eliade as well as Tylor, Bultmann reads myth symbolically. In Bultmann's excruciatingly misleading phrase, one must 'demythologize' myth, by which he means not eliminating myth but on the contrary extricating its true, symbolic subject matter. Once demythologized, myth is no longer about the external world and is instead about the place of human beings in that world: "The real purpose of myth is not to present an objective picture of the world as it is, but to express man's understanding of himself in the world in which he lives." "Myth should be interpreted not cosmologically, but anthropologically, or better still, existentially" (Bultmann, 1953: p. 10).

Read literally, the New Testament describes a cosmic battle of good and evil anthropomorphic gods for control of the physical world. These gods intervene miraculously not only in the operation of nature but also in human lives. Humans are therefore not responsible for their actions. Demythologized, the New Testament still refers in part to the physical world, but now to a world ruled by a single, nonanthropomorphic, transcendent God. Because God does not act directly in the world and because no evil powers exist, humans are free and therefore responsible for their actions. Because a literal interpretation reduces humans to the pawns of larger, competing forces, it concentrates on those forces, which means on the world. Because a symbolic interpretation pronounces humans free, it concentrates on the actions they choose in response to the world.

Yet myth demythologized is not merely about humans, which would be myth 'psychologized.' It is about the human experience of the world. It is the depiction of a world view. For secular existentialists like Camus and Jean-Paul Sartre, the world experienced is godless and indifferent to humans. For Christians, according to Bultmann, the world experienced is safe and just. But the world can be comforting only insofar as God still intervenes in the world – for example, to save an ill child, which is Bultmann's own example. But then Bultmann's demythologizing proves inconsistent: God does not operate in the world in a way contrary to science. Otherwise moderns could not still have myth. Yet God does operate in ways that demonstrate his concern. Otherwise the world would be godless.

Demythologized, myth ceases to be purely primitive, as for Tylor, and becomes universal, as for Eliade. Myth ceases to be false, as for Tylor, and becomes true. Where Eliade invokes the existence of modern myths as *ipso facto* evidence of the compatibility of myth with science, Bultmann actually tries to reconcile myth with science, successfully or not. Where Eliade claims that moderns have myths of their own, Bultmann claims that moderns can retain biblical myths. He seeks to reconcile the Bible with science rather than, like Eliade, to uncover distinctively modern, seemingly secular myths.

Bultmann's boldest response to Tylor is to circumvent the function of myth. In translating the meaning of myth into terms acceptable to moderns, he sidesteps the issue of why moderns, even if they can have myth, need it. Unlike other symbolic interpreters of myth such as the religious philosopher Paul Ricoeur (1967) and the philosopher Philip Wheelwright (1968), Bultmann never maintains that the meaning of myth is untranslatable into nonmythic terms. Taking the meaning of myth from philosophy, he never asks why myth is needed.

Like Bultmann, Jonas seeks to show that ancient myths have an eternal meaning that speaks to moderns. For both Bultmann and Jonas, myth describes the alienation of humans from the world as well as from their true selves prior to their acceptance of God. Because Gnosticism, unlike mainstream Christianity, is radically dualistic, humans remain alienated from the physical world and from their bodies even after they have found the true God. Gnostics find the true God only by rejecting the false god of the physical world.

Unlike Bultmann, who wants to bridge the divide between Christianity and modernity, Jonas acknowledges the divide between Gnosticism and modernity. In Gnosticism the state of alienation is temporary. In modern, secular existentialism alienation is permanent. Alienation is the human condition, not a fall from it. What Jonas 'demythologizes' is not the source of alienation or the solution to it, for there is neither source nor solution, but the fact of alienation. He translates Gnostic myths into existentialist terms not to make Gnosticism palatable to moderns but only to show the similarity between the Gnostic and the existentialist outlooks: "the essence of existentialism is a certain dualism, an estrangement between man and the world …. There is only one situation … where that condition has been realized and lived out with all the vehemence of a cataclysmic event. That is the gnostic movement" (Jonas, 1963: p. 325). To parallel Gnosticism to modern existentialism, he must ignore the heart of Gnostic mythology – the elaborate cosmogony – and limit himself to the present state of the world. Like Bultmann, Jonas bypasses the function of myth and confines himself to the meaning.

Myth as Both Other than Explanatory and Other than Literal

The most radical departures from Tylor transform both the explanatory function and the literal meaning of myth. The most influential theorists here have been depth psychologists, Sigmund Freud (1856–1939) and C.G. Jung (1875–1961). For both, the subject matter of myth is the unconscious, and the function of myth is to express the unconscious.

The psychologizing of myth does not begin with Freud or with Jung. The recognition that myth involves the projection of human qualities onto gods goes back to at least the pre-Socratic philosopher Xenophanes, who, writing in the sixth century BC, observed that Ethiopians imagine their gods to be swarthy and flat-nosed, whereas Thracians visualize their gods as fair-haired and blue-eyed. Most famously, Xenophanes asserted that if lions, horses, and oxen had gods, their gods would look like them. Jung in particular is eager to trace a psychological understanding of myth all the way back to ancient Gnostics and to medieval alchemists. Going beyond – and against – Xenophanes, he claims that ancient myth tellers themselves often recognized the psychological meaning of their myths.

Nevertheless, for Freud and Jung alike, the key intellectual accomplishment of modernity has been the disentanglement of the psychological from the physical and the metaphysical – the disentanglement of the inner from the outer. Projections onto the outer world, which had taken the form of gods and of myths about gods, have largely been withdrawn. The outer world has come to be recognized as a natural rather than a supernatural domain, to be explained by impersonal scientific laws rather than by the decisions of gods recounted in myths. For both Freud and Jung, the rise of science has spelled the fall of religion and of religious myths.

Because the unconscious for Freud is composed of repressed sexual and aggressive drives, myth functions to release those drives in a disguised, vicarious way, so that the creator and the user of a myth need never confront its meaning and thereby their own nature. Myth, like other aspects of culture, serves simultaneously to reveal and to hide its unconscious contents. The classic psychoanalytic study of myth is that of Freud's one-time disciple Otto Rank (1884–1939). Focusing on myths of male heroes, Rank sees the myths as providing an unconscious, vicarious fulfillment of Oedipal drives. Myth serves neurotic adult males fixated at their Oedipal stage: "Myths are, therefore, created by adults, by means of retrograde childhood fantasies, the hero being credited with the myth-maker's personal infantile [i.e., childhood] history" (Rank, 1914: p. 82).

Contemporary psychoanalysts like Jacob Arlow take myth positively rather than negatively. For them, myth helps solve the problems of growing up rather than perpetuating them. Myth is progressive rather than regressive, and abets adjustment to society and the outer world rather than childish flight from both. Myth serves less to vent repressed drives than to sublimate them: "Accordingly, the myth can be studied from the point of view of its function in psychic integration – how it plays a role in warding off feelings of guilt and anxiety, how it constitutes a form of adaptation to reality and to the group in which the individual lives, and how it influences the crystallization of the individual identity and the formation of the superego" (Arlow, 1961: p. 375).

Jungians have taken myth positively from the outset. For them, the unconscious expressed in myth is not the Freudian repository of repressed, antisocial drives but a storehouse of innately unconscious 'archetypes,' or sides of the personality that have simply not had an opportunity at realization: "Contents of an archetypal character … do not refer to anything that is or has been conscious, but to something essentially unconscious" (Jung, 1968: p. 156). Myth is one means of encountering this Jungian, or 'collective,' unconscious. The function of myth is less release, as for classical Freudians, than growth, as for contemporary ones. But growth means less adjustment to the outer world, as for contemporary psychoanalysts, than cultivation of the 'inner world.' The payoff is self-realization. Some Jungians and Jungian-oriented theorists like the American Joseph Campbell (1904–87) so tout the payoff of myth that it becomes a panacea for all humanity's problems. Jung himself never goes this far. For Jung, myth works best as part of therapy. For Campbell, myth fends off the need for therapy.

Campbell (1949) differs most with Jung over the origin and function of myth. Where for Jung the archetypal contents of myth arise out of the unconscious, only in some works of Campbell's do they do so. Even then, sometimes for Campbell the unconscious is acquired rather than inherited – a view similar to freud's. At other times the contents of myth emerge from the imprint of either recurrent or traumatic experiences. In all of these cases each society creates its own myths – whatever the source of the material it uses. In contrast to Jung, Campbell is sometimes a diffusionist: myths originate in one society and spread elsewhere.

Campbell comes to declare repeatedly that myth serves four distinct functions: to instill and maintain a sense of awe and mystery before the world; to provide a symbolic image for the world, such as that of the Great Chain of Being; to maintain the social order by giving divine justification to social practices like the Indian caste system; and most of all to harmonize human beings with the cosmos, society, and the parts of themselves. Despite conspicuous differences, Campbell stands close to Jung and stands closest in '*The Hero with a Thousand Faces*' (1949), which remains the classic Jungian analysis of hero myths.

By far the most radical innovation in the Jungian theory of myth has been the development of 'archetypal' psychology, associated with James Hillman. Archetypal psychology faults classical Jungian psychology on multiple grounds. By emphasizing the compensatory, therapeutic message of mythology, classical Jungian psychology purportedly reduces mythology to psychology and gods to concepts. In espousing a unified self, or 'Self,' as the ideal psychological authority, Jungian psychology supposedly projects onto psychology a Western, monotheistic, Protestant outlook. The Western emphasis on progress is purportedly reflected in the primacy that Jungian psychology accords hero myths and in the primacy that it accords the ego, even in the ego's encounter with the unconscious: the encounter is intended to abet development. Finally, Jungian psychology is berated for placing archetypes in an unknowable realm, distinct from the knowable realm of symbols.

As a corrective, Hillman and his followers advocate that psychology be viewed as irreducibly mythological. Myth is still to be interpreted psychologically, but psychology is itself to be interpreted mythologically. One grasps the psychological meaning of the myth of Saturn, a favorite Roman god of

Hillman's, by imagining oneself to be the figure Saturn rather than by translating Saturn's plight into clinical terms like depression. At the same time the depressed Saturn represents a legitimate aspect of one's personality. Each god deserves its due. The psychological ideal should be pluralistic rather than monolithic – in mythological terms, polytheistic rather than monotheistic. Insisting that archetypes are to be found *in* symbols rather than outside them, Hillman espouses a relation to the gods in themselves and not to something beyond them. The ego becomes but one more archetype with its attendant kind of god, and it is the 'soul' rather than the ego that experiences the archetypes through myths. The payoff is a esthetic rather than moral: one gains a sense of wonder and contemplation, not a guide to living.

Recent Theories of Myth

The most notable recent theories of myth have been variations on myth as primitive science, theoretical and applied. Cognitivists led by the French anthropologist Pascal Boyer (1994) analyze the mental processes that shape thinking processes far more rigidly than Tylor's open-ended sequence of observation, analogy, and generalization. Cognitivists investigate the constraints on mythic explanations more than the explanations themselves. The German classicist Walter Burkert and the French literary critic René Girard have revived the theory that ties myth to ritual. Where for Frazer and his English follower Lord Raglan (1936) myth is the script for the ritualistic killing of the king, whose death and replacement ensure the rebirth of crops, for Burkert myth reinforces the ritual that commemorates the past hunting of animals. The function of myth is not physical but psychological and social: to cope with the guilt and anxiety that members of society feel toward their own aggression and to unite society by turning that aggression onto outsiders (see Burkert, 1996). Where for Frazer and Raglan the king is heroic because he is willing to die for the sake of the community, for Girard the hero, who can range from the most marginal person to royalty, is killed or sometimes exiled as a scapegoat for violence in society. Rather than directing the ritualistic killing, as for Frazer and Raglan, myth for Girard arises afterward to cover it up by making the victim first a criminal and then a hero. The function of myth is social: to preserve the ethos of sociability by hiding not only the killing but more deeply the violence endemic to society (see Girard, 1972).

Bringing Myth Back to the World

Where theorists of the nineteenth century assumed that myth could not be dislodged from the world and therefore could not be saved from science, theorists of the twentieth century saved myth from science either by removing myth altogether from the world or by removing it as an explanation of the world. The question for the twenty-first century is whether myth can be returned to the world – but in a way still compatible with science. The postmodern dismissal of the authority of science, evinced in the labeling of science as itself mythic, cheapens both myth and science. Twentieth-century theorizing commendably sought to accommodate myth to science rather than to spurn science in the name of myth.

One possible way of bringing myth back to the world is through the application to myth of D.W. Winnicott's notion of play. Winnicott did not himself analyze myth, but his analysis of children's play and of its continuation in adult make-believe provides one road back to the world. For Winnicott, play is *acknowledged* as other than reality: children grant that they are just playing. But play is no mere escapism. It involves the appropriation of reality for oneself. To pretend that a spoon is a train is to take a spoon and to turn it into a train. Far from confusing itself with reality, play demarcates the difference. Play grants itself the right to treat a spoon as a train, and a parent is barred from asking whether the spoon really is a train. Once play is over, the train is again a mere spoon.

As adult extensions of play, Winnicott names gardening and cooking and more deeply art and religion – in all of which one constructs a world out of elements from the outer world: "It is assumed here that the task of reality-acceptance is never completed, that no human being is free from the strain of relating inner and outer reality, and that relief from this strain is provided by an intermediate area of experience which is not challenged (arts, religion, etc.). This intermediate area is in direct continuity with the play area of the small child who is 'lost' in play" (Winnicott, 1982: p. 13).

Myth, or at least some myths, may be considered as adult make-believe (see Segal, 2003: pp. 154–157). For example, in films, film stars, like gods, can do all kinds of things that celebrities who perform in person cannot. And in a movie theater they are gargantuan in size. In all of these ways film stars fit the popular conception of gods, which is one of degree rather than of kind. God, like humans, has a body, but it is bigger. On screen, merely human virtues get magnified into superhuman ones: bravery becomes fearlessness, kindliness becomes saintliness, strength becomes omnipotence, wisdom becomes omniscience. Film stars are 'idolized' and 'worshiped,' and the greatest are called 'gods.' As 'stars,' they shine brightly in a heaven far above us.

It might understandably be argued that even if film stars are godlike in their attributes, worshipping them still does not restore divinity to the physical world. Yet stars who take responsibility for accomplishing things in the social and even the physical world are often more successful than whole nations, such as in canceling Third World debt, responding to famine, and saving the environment.

Against my argument that film stars are the modern, secular version of gods, it might sensibly be observed that these days nobody believes the hype. But this hard-nosed view of present-day fans is the naive one. Fans continue to 'idolize' and 'worship' stars not in ignorance of their flaws but in defiance of them. The flaws are either denied or discounted. But the devotion of fans is not mindless. It is done knowingly. It is, following Winnicott, make-believe not credulity. The myths of movie stars are their films and their idealized biographies. Taking those biographies as make-believe reconnects myths to gods, therefore to religion, and therefore to the world.

Myths and Symbols: Organizational

Pasquale Gagliardi, Catholic University, Milano, Italy; and Fondazione Giorgio Cini, Venezia, Italy

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In what follows, the essential features of 'organizational symbolism' are first described, since this has been the intellectual context within which the constructs analyzed have largely been developed. As this distinctive stream of inquiry, within the field of organization studies, focuses on the expressive – as opposed to the instrumental, pragmatic – dimension of organizational life, the author analyzes the nature of (and the tensions implied by) the interrelations between productive and symbolic practices. Recent developments and methodological innovations in the field are also discussed. The article describes then the main traits and functions of different organizational symbols – language and linguistic constructs (myths), (ritual) behaviors, and objects/artifacts. Special attention is paid to the role of saga – defined as a collection of myths – in the process of institutionalization and in shaping organizational identity. Finally, the origin and function of mediatory myths in managing the dialectic relation between organizational ideology and operational needs are highlighted.

Organizational Symbolism

The constructs 'organizational myth' and 'organizational symbol' first made their appearance in organizational and managerial studies in the second half of the 1970s, at a time of renewed and rapidly spreading interest in the cultural study of organizations. This interest was manifest in two main currents of study: the interorganizational perspective of 'new institutionalism' (Powell and DiMaggio, 1991), which explored the ways in which cultural values shape organizational forms – and induce the organizations that populate a particular 'field' (a territory, an industrial sector, or a distinct sphere of institutional life) to grow similar rather than dissimilar – and the microperspective of 'organizational symbolism' (Dandridge et al., 1980; Turner, 1990), which viewed individual organizations as 'cultures' characterized by distinct paradigms, to be then analyzed not only in their instrumental and economic aspects but also in their ideational and symbolic ones, using holistic and interpretative research models.

Born at the end of the 1970s as a marginal and nonconformist phenomenon, organizational symbolism rapidly grew into one of the main currents of thought in organizational studies. It produced an extraordinary flourishing of studies and research, gaining unusual popularity even outside the academic sphere. Most notable among the numerous surveys of this body of literature are the following: Alvesson and Berg (1992), a particularly thorough treatment which reviews the various theoretical perspectives that have developed internally to the movement, and discusses the relevance of symbolism to managerial practice; the study by Trice and Beyer (1993), which provides a detailed picture of the material set out in numerous empirical research studies; and the work of Jones (1996), which gives an overview of the main methodological issues connected with the study of organizational symbolism.

Although the approach employed by the movement's exponents was often presented as radically innovative, it was in fact deeply rooted in the social sciences. Despite their frequent use of anthropological terms and concepts, scholars of organizational cultures more frequently acknowledge their intellectual indebtedness to certain currents of sociological thought – in particular to phenomenological sociology, symbolic interactionism, ethnomethodology, and above all to the great ethnographic tradition of urban and occupational sociology (e.g., Whyte, 1955; Roy, 1961). However, although an approach inspired by the same theoretical ideas had already been used in the study of formal organizations (see, in particular, Selznick, 1949; Gouldner, 1954; Crozier, 1963), until the early 1970s organizational and managerial studies were indubitably dominated by a rationalist and positivist paradigm which viewed the analysis of relations among objective and measurable variables as the central concern of research and substantially neglected the notion of culture. Ironically, many of these analyses were conducted in the name of Max Weber, regarded as the founding father of organizational theory, but they ignored Weber's invitation to see organizations as the expression of cultural values, interpreting his bureaucratic model instead as the organizational model *par excellence* and with no alternatives (Clegg, 1995). In one of the first essays devoted expressly to organizational symbolism, Dandridge et al. (1980) wrote that: "… a survey of major texts within the field of organizational behavior establishes clearly that there are virtually *no* references to the phenomenon that is the subject of this paper … For all practical purposes … it is as if the phenomenon did not exist or was not important." In effect, in those years the statement that organizations have their own myths and symbols would have seemed at most a paradox, almost an oxymoron, to the extent that formal organizations – especially economic ones – were regarded as utilitarian forms of social aggregation in which individual and collective behaviors were governed mainly by norms of instrumental rationality (*see* Organization: Overview). If modern organizations are, by definition, the domain of a legal-rational ethos, and characterized by pragmatic behaviors shaped by the practical goals to which they are directed, how can these organizations possibly harbor expressive and disinterested behaviors shaped by impulses and emotions? And if these forms of behavior do exist, how can they be anything but secondary, irrelevant, or at any rate dysfunctional and therefore to be eliminated? Organizational symbolism challenges these prevalent opinions and invites us to read organizations in a completely different light. As Turner (1990) observes, "… the current growth of interest in organizational symbolism and corporate culture points to the end of an era. Looking anew

at the organizational world we can see that it is a sensual and emotional realm, replete with its own ceremonies, rites and dramas."

The cultural approach asserts that every productive practice is determined equally by the practical requirements from which it springs and by particular visions of the world. No productive practice is only and exclusively such, for it is simultaneously a symbolic practice, a way to appropriate reality by imposing one's own specific view of what reality is. Accordingly, scholars of organizational cultures have explored the interweaving of technical requirements and expressive needs, the ritualistic significance of apparently rigorously pragmatic behaviors and processes, and the overlapping of ideological prejudice and mythic knowledge with scientific expertise. In other words, they have shown that culture and utility are woven together in even the most strictly utilitarian forms of social aggregation. From this perspective, therefore, organizations – and their environments – are conceived as 'symbolic fields': that is, as intersubjectively negotiated systems of meaning recognizable in a coherent set of symbols or conventional representations of important and complex aspects of organizational and social reality. Decoding an organization's symbolic field involves analysis of its answers to such fundamental questions as, for example, the reliability or unreliability of human beings, the symmetry or asymmetry of social relations, the type of relationship – dominance, harmony, or subordination – with the external environment, and the nature of reality and of truth.

In the early 2000s, the study of organizational symbolism and corporate cultures gradually lost the popularity and central role it had built up in the previous 20 years. At first glance, intellectual movement seems to have become marginal to organizational studies and to have run out of innovative steam. Yet, on closer examination, it has not disappeared but has gradually been replaced by (1) currents of parallel studies that came into being and thrived in a general climate of epistemological renewal encouraged by the symbolist movement; and (2) thematic studies that grew as offshoots from the mature branch of studies focused on organizations as cultures.

Among the parallel movements that organizational symbolism contributed to legitimize it is worth mentioning the narrative approach (Czarniawska and Gagliardi, 2007), which emphasized the importance of the stories and myths produced in organizations and explored the analogy – proposed by Ricoeur (1981) – between text (narrating) and action (organizing): "The raw material of everyday organizational life consists of disconnected fragments, physical and verbal actions that do not make sense when reported with simple chronology. Narrating is organizing this raw and fragmented material with the help of such devices as plot and characters. Simultaneously, organizing makes narration possible, because it orders people, things and events in time and place." (Czarniawska and Gagliardi, 2007, p. VII).

The most striking of the thematic studies that developed within the symbolist movement is so-called organizational aesthetics. This approach sets out to study the role of sensory experience in the daily life of organizations; that is (1) (tacit) aesthetic knowledge as opposed to intellectual knowledge; (2) disinterested, 'expressive' action shaped by the emotions, as opposed to 'impressive' action that can be recognized in terms of the practical aims that it focuses on; and, finally (3) aesthetic communication, seen as the set of modes whereby sensory experience – by nature ineffable – is conveyed and shared. The development of this current of thought has been enhanced by the study of artifacts, one of the three fundamental symbolic systems that can be used – as we see in the next section – to express the beliefs and values of a culture. Although some remarks on the importance of the aesthetic dimension of organizations were conducted slightly earlier (e.g., Ramirez, 1991), there has been a growing production of literature on the subject since the late 1990s (Strati, 1999; Linstead and Hoepfl, 2000; Guillet de Monthoux, 2004; Gagliardi, 2006). Its aim is to explore the methodological implications of a specifically 'aesthetic' approach to the study of organizations, as a distinct research field. Organizational aesthetics is in fact solidly rooted in the cultural-symbolist movement without, however, sharing its predominant cognitivist stance (Gagliardi, 2006).

Organizational Symbols: Types and Functions

The definition of 'symbol' most widely used by scholars of organizational cultures is the one provided by Cohen (1976): "Symbols are objects, acts, relationships or linguistic formations that stand ambiguously for a multiplicity of meanings, evoke emotions, and impel men to action." Organizational symbols normally are grouped into three categories corresponding to the three main systems for expressing beliefs and cultural values within an organization: verbal language, behavioral language, and the language of objects.

Verbal Symbols

Principal among verbal symbols is language itself, with its ability to categorize and articulate experience using specific 'jargons,' which may differ even among organizations operating in the same context and speaking the same language. The category of verbal symbols also comprises linguistic artifacts like legends, stories, slogans, the names given to places, persons, events, and myths. The latter can be defined as dramatized accounts of events whose veracity is asserted as dogma, or is taken for granted, and which have the effect of legitimating and making desirable the behavior enacted in the events narrated and the ideas from which such behavior springs. To the extent that the cadence of organizational life is set by the alternation of crucial experiences – which jeopardize its identity and sometimes its very survival – with periods of relative stability, myths are often the idealization of the specific ways in which those difficulties have been overcome, and they shape the routines that orient behavior during periods of stability. Consequently, the myths most frequently encountered in organizations relate to their birth (myth of the origin) and to the transformations induced by traumatic events (the death of the founder, for example, or a slump in the market). In all organizations, the beliefs and values that myths embody exert a pervasive influence on decisions (*see* Organizational Decision Making), and it is difficult not to discern an element of 'mythic knowledge' even in decisions apparently taken solely on technical–scientific grounds. However, it has been pointed out that the more decisions are operational, and the effects of actions measurable, the more decisions are taken following

principles of instrumental rationality, and the broader the range of options and viable choices available. By contrast, the more choices are general and tied to the base values on which the organization grounds its identity, the more restricted the range of options, and the more mythical, prescientific, and unamenable to the scrutiny of reason and experience becomes the knowledge utilized (Gagliardi, 1986).

Symbolic Actions

Of particular importance among the symbolic manifestations represented by acts and styles of behavior are rites and ceremonials as emotionally charged collective actions – usually performed in a rigorously prescribed sequence – by means of which an organizational community celebrates its successes, heroes, and organizational ideals. Various classifications of organizational rites – which assume a wide variety of connotations – have been proposed, as well as analysis of their manifest and covert cultural consequences (Trice and Beyer, 1984). Among the most frequently observable rites are:

1. rites of passage (e.g., training seminars as a prelude to a promotion), which ease the transition of individuals to new roles and status;
2. rites of enhancement (like the awarding of bonuses for outstanding performance), which consolidate the social identities of the rewarded and induce others to emulate them;
3. rites of degradation (like the replacement of senior managers for some reason deemed unworthy), which solemnly and publicly reaffirm the importance of the social roles compromised by the behavior of the persons degraded;
4. rites of integration (like the celebrations organized by businesses on special occasions like Christmas or the anniversary of the company's foundation), which encourage shared feelings of equality and participation in a common enterprise, temporarily suspending the norms which sanction differences in power and status, but implicitly reaffirm the adequacy of those rules in day-to-day life;
5. rites of renewal (like the periodic drawing up of strategic plans), which reassure the organization's members that it is by keeping up with the times that present problems will be overcome, but at the same time bolster the legitimacy of existing systems of power and authority.

Artifacts and Aesthetic Knowledge

A third system of symbols is constituted by material artifacts or the intentional products of human action which exist in the organization independently of their creator and which can be perceived by the senses: products, images, buildings, furnishings, arrangements of physical space. Given the durability of physical matter, artifacts are able tenaciously and incessantly to transmit particular messages and cultural stimuli, thereby encouraging the diffusion and sharing of special 'modes of feeling' in ways that are all the more efficient because they evade intellectual control (Gagliardi, 1990).

The advent of organizational aesthetics has given/received a great boost to/from the study of corporate artifacts as vehicles of sensory knowledge and what is defined as 'corporate pathos'; that is, the specific 'way of feeling' cultivated and transmitted in the culture of each organization. Artifacts include a category that has recently been the focus of considerable attention: images. This highlights the increasingly important role of visual methods in organizational research (Warren, 2009), a trend in line with the development of "a mass-mediated, image-saturated society where aesthetic appeal is an increasingly important arbiter of economic value" (Warren, 2009, p. 566). Images are above all visual but we can also speak of auditory, tactile, and olfactory images in order to refer to distinctive combinations of sensible experiences recognizable through senses other than sight. The heuristic potential of images – in this wider definition – derives from their capacity to elude the restraints of descriptive language (which only allows us to say one thing at a time) and enables the use of a 'presentational' language (which allows us to say several, even contradictory things simultaneously, thus conveying knowledge by acquaintance, which eliminates the filter of abstraction) (Bruner, 1962; Langer, 1969).

The growing importance attached to the study of artifacts, to the structuring of space and the sensory experiences that they encourage or hinder has led to deep innovations in ethnographic practice. It has also meant breaking the monopoly of traditional fieldwork techniques and has highlighted the indispensable role of the researcher's 'sensuality' as an epistemological disposition and vital tool in understanding reality (Fine, 1996; Stoller, 1997).

The Role of the Saga in the Process of Institutionalization

The organizational myths of origin and transformation are often blended together in a 'saga' or an account of an 'extraordinary' series of events which traverses and unifies the various phases of the organization's evolution. In a saga, historical facts are embellished by subsequent re-elaborations, inconsistencies are eliminated or justified, and the rational explanation of how certain means lead to certain ends acquires an affective connotation which transforms the workplace into a loveable and loved institution. The saga therefore performs an essential role in the process of institutionalization: that is, in the process by which the organization, from a sterile mechanical apparatus for the efficient distribution and coordination of tasks, becomes imbued with values and acquires a distinctive 'character'. This character on the one hand underpins the collective identity and sentiment of belonging of the organization's members, while on the other it legitimates the organization in the social environment (Selznick, 1957). "Whether developed primarily by management or by employees, the story helps rationalize for the individual his commitment of time and energy for years, perhaps for a life-time, to a particular enterprise. Even when weak, the belief can compensate in part for the loss of meaning in much modern work, giving some drama and some cultural identity to one's otherwise entirely instrumental efforts. At the other end of the continuum, a saga engages one so intensely as to make his immediate place overwhelmingly valuable. It can even produce a distortion, with the organization becoming the only reality, the outside world becoming illusion" (Clark, 1972).

To the extent that the saga generates a shared conviction that the organization is unique because it has been the protagonist

of an unusual enterprise crowned by extraordinary success – a conviction which induces individuals to remain within the system, endeavoring to improve it rather than pursuing their interests elsewhere – the saga may constitute a precious organizational resource. Indeed, ensuring the stable participation and constant commitment of its members is one of the crucial problems faced by any co-operative system constructed to pursue specific ends.

Mediatory Myths

In that, as mentioned in the first section, the dialectical relation between expressive needs and pragmatic exigencies unavoidably conditions the lives of organizations; a further crucial organizational problem is the management of the contradictions, tensions, and psychological costs that derive from that relation: mediatory myths are discursive formulations which make contradictions acceptable.

Unlike the myths of origin and transformation, which mainly orient actions to be undertaken, mediatory myths provide retrospective justification for previous actions and states of affairs. The need to justify concrete action arises, first, from the fact that different values may conflict in specific situations – and it is difficult to comply with one principle without being in breach of another – and second from the fact that actions always tend, actually or apparently, to fall short of the ideals that have inspired them, so that there is invariably a gap between 'what we should do' and 'what we are able to do,' between the purity of the ideal and the impurity of the concrete organizational practice. Mediatory myths harmonize conflicting principles, not by means of logical arguments but by means of assertions of fact, and they resolve or reconcile contradictions by simply denying and inverting them, or by holding irreconcilable alternatives in suspension. Abravanel (1983) reports an interesting example of a mediatory myth: that of the 'wild ducks' institutionalized at IBM when T.J. Watson Jr. was chief executive officer. The contradiction between the ideology encouraged by Watson, namely that the company's employees were free to express their individuality, and a corporate reality characterized by rigid training and socialization practices was resolved by institutionalizing the myth that the employees were like wild ducks: they could not be tamed but nevertheless flew in formation and did not choose their migratory route.

Names and Naming

Abstract

The category 'personal name' describes a centrally important aspect of all known forms of human life, even if the actual way such names are attributed and used has varied immensely from region to region and across time. People start working on their names as they enter language and sociality. Therefore, our names carry within them specific, localized histories of personhood and belonging, both collective and singular. This article focuses on the ways in which names are functionally diverse, how they reflect our collective belongings, how they position us by relation to other people, namely in terms of hierarchic relations, and how they alter during the person's life course.

From an anthropological, comparative point of view it can be securely stated that the analytic category 'personal name' is indispensible. It describes a centrally important aspect of all of the different styles of human existence that anthropologists and historians have recorded over the years. While specific processes of personal naming vary widely from context to context and across time, the near omnipresence of modes of naming personal singularity cannot be doubted. Human ways of life are both social *and* personal, and naming is one of the central aspects through which the two imply each other (Rorty, 1969).

Personhood is the mold within which humans enter humanity – that is, it is the central pathway to reflexive thinking and, therefore, to human sociality (Mauss, 1985[1938]). Persons are called into personhood by other persons with whom they are in close contact (Trevarthen, 1998), and there are no human forms of collective experience that do not rely on the agency of persons who are aware of themselves as somehow singular – as Godfrey Lienhardt put it, "one can lay too much one-sided stress on the collectivist orientation of African ideas of the person. (…) the recognition of the importance of an inner, mysterious *individual* activity, comparable to what is meant by speaking in English of 'what goes on inside' a person is attested by many proverbs" (Lienhardt, 1985: 145).

Self-building is both a condition for language and a result of language. People start working on their own personhood as they enter language. Thus, the diverse modes in which languages differentiate subject positions affect people's awareness of their own personhood. Personal naming cannot be dissociated from the way in which languages use pronouns (Benveniste, 1966: 251–257) and conjugate verbs, as Socrates pointed out so long ago (cf Ademollo, 2011). While there may be occasions in which singular persons remain unnamed, and while there are contexts in which personhood is subordinated to collectivity, the dissolution of personal singularity cannot ever be absolute, as that would imply a step out of language. This means that personal naming is a central aspect of human sociality wherever the latter may be found.

Furthermore, naming systems reflect the fact that humans are called into humanity by other humans in an always previously inhabited world: alterity is always anterior to identity and between the two there is no symmetry (Lévinas, 1996). This means that plurality is recurrent in human life (Marriott, 1976); human singularity is never stable, never complete, and it emerges within intersubjectivity out of the contagion and contrast of different anterior singularities, as Freudian thinkers have long identified (Butler, 2012; Winnicott, 1971).

Naming systems reflect such processes in many, historically differentiated ways. Our names carry within them specific, localized histories of personhood, both collective and personal, but always anterior to the emergence of each one of us as persons. Thus, our names are seldom unique – as they would be if we were named by a conjugation of numbers in an infinite series. As it happens, reificatory modes of naming of this nature have been tried out, but they have been experienced always as being repressive. They work against the person's immersion in anterior pluralities; by negating the person's history, they negate the person.

Naming is, in this way, a deeply ambiguous phenomenon, since we both accept and acknowledge our names. Naming is fully part of the intersubjective experience and is acquired in an interpersonal way. Fully private names (those of which only the named would be cognizant) must be left out of the broad analytic category of personal names.

Since coevals are named in broadly similar ways, they tend to share more or less similar paths of ontogenesis (histories of personal constitution – Toren, 2002). It is because our names echo other people's that they are recognizable as meaningful human names. People whose names somehow fail to conform to the norm, or are incomplete, or absent in significant ways,

are prone to be pulled out of ordinary personhood, even to experience stigma. Naming traditions play on differentiation and identification to create naming systems. Moreover, systematicity in naming may result from denotational as well as connotational processes (Lévi-Strauss, 1966). Most frequently, naming systems take recourse to a conjugation of both. Very seldom are personal names so utterly meaningless as to lack any reference whatsoever to aspects of the world that are seen to complement the person's personhood.

The list of possible personal naming systems must remain open-ended, as the history of human creativity has not yet finished. There are, however, a number of forms of constituting systematicity in personal naming that are very recurrent in the anthropological and historical record. In the sections that follow, I will attempt to outline some of the most common of these.

Functional Diversity

Types of names differ depending on the purposes for which they have been conceived and the manner in which they are supposed to be used, so that it is common for people to be named differently in different contexts, depending on circumstances (either through utterly different names or through different variations of what is considered to be 'the same name' – e.g., as in Jack and John, Sue and Suzanne, etc.). In the great Eurasian region, as in most other social contexts where an administrative apparatus is present, one frequently encounters naming systems that are centrally structured by a major distinction between proximity naming and formal naming (that is, the name that the State condones). Often, the latter is treated as having greater externality, truthfulness, or objectivity (Pina-Cabral, João de, 2010a). Thus, typically, formal names are seen as being more immune from change as opposed to 'nicknames,' 'home names,' 'little names,' etc., which are seen as mutable and prone to varying depending on the interlocutors' particular relation (Segalen, 1980; Manning, 1974).

Hierarchy and kinship play here a central role and are often reflected in forms of name declination: hypocoristics, diminutives, and suchlike. Similarly, *noms de guerre* or professional names are also very commonly encountered. The usual example here is the practice of modern armies to choose a simplified version of each soldier's formal name so that (1) soldiers' names are simple and (2) there are no two soldiers in a battalion called in the same way. In Iberian societies (and in others such as Morocco or Russia) where official names are often perceived as being too long or too formal for daily use, adults are prone to develop *noms de guerre* that they use in their more common daily encounters. There is continuity between this practice and that of taking recourse to functionally specific pseudonyms: that is, names that are used for specific purposes, elaborating a dramatized fiction of split personhood (that this is treated as a fiction remains implicit in the 'pseud-').

Wherever Western European modes of naming have been adopted around the world, there is a tendency to believe that naming has the primary function of individuating the person. This theory, however, can hardly withstand analytic inquiry (Pina-Cabral, João de, 2012). Plurality and singularity are constantly at play in personhood, but plurality is always anterior and singularity never fully achieved.

Collective Naming

Persons often take on a combination of names some of which are more singularizing while others are specifically geared at reflecting collective belonging. In the broad mass of Eurasian societies, it is very common for personal names to be differentiated between proper name and surname (so as to simplify, I use here the English form of the distinction, but it must be noted that the meaning of the terms used to describe the two kinds of names varies immensely, with significant implications, even within Western Europe). In fact, this broad differentiation is far less rigid and homogeneous than it is usually thought to be: surnames can be of many kinds; proper names are formed in many different ways; and between the two there can exist third type of names (as, for example, the interesting English category of 'middle names,' or Russian patronyms, or still Basque household names) (for collections emphasizing naming diversity, see Tooker and Conklin, 1984 or vom Bruck and Bodenhorn, 2006). Surnames as we use them today in our passports are a relatively recent phenomenon and ones that are still not universally applied, although it would seem that the demands of modern travel are quickly changing that. In Western Europe, surname systems differ profoundly, namely between those that are strictly patrilineal (as in the United Kingdom or France – and this is something that is also quickly changing due to feminist activism) and those that are loosely bilateral (as in the regions where Iberian languages are spoken).

People can take on names that reflect house belonging, familial belonging, descent group belonging, village belonging, local group belonging, ethnic group belonging, etc. The relation between such collective naming practices and State-condoned formal names can also differ profoundly from context to context defying generalization. Things like clan names and lineage names can mix with and approximate titles, particularly in elite contexts. Names often are treated as prized possessions.

Again, to the contrary, in the case of deeply subaltern persons (such as slaves and outcasts) the way they are named often reflects their own subalternity (Benson, 2006) – for example, in eighteenth- and nineteenth-century Brazil, slaves used the surnames of the masters and their children inherited such surnames, so that, today, the fact of a black person inheriting a classic upper-class Portuguese surname can be taken to signify slave ancestry. The most extreme example of name oppression through name denial is probably what was attempted by the Austrian State during World War II (1938, the year Mauss delivered his famous article on the person), when all Jewish citizens were denied a surname and forced to adopt the same name, Israel for males and Sarah for females. Their birth registries were stamped over in red with these names.

Aristocrats often use different naming systems from commoners thus creating ready modes of signaling status. In contemporary metropolitan contexts, it is common for different ethnic groups to take recourse to different name series,

thus allowing for ready differentiation. But the use of *noms de guerre*, pseudonyms, and other more informal naming systems also often reflects collective belonging. This may be either through serial linking – as in the broad family of teknonyms (Mary's mother, John's father, etc.) or in group form (as in 'John of Musgrove,' where Musgrove is the name of a village or a household). Such naming processes are usually very sensitive to the interlocutors' relative status. In particular, nicknames (again I take recourse to an English shorthand for what is a very diverse family of informal forms of naming) can be either group names or more individuating names (in the Iberian Peninsula, for example, the way nicknaming is practiced differs profoundly from region to region – Pina-Cabral, João de, 1984). Such names may be comical or somehow demeaning and can be more or less readily accepted by the named person. Hypocoristics and diminutives usually bear within them some mark of the emotional or moral quality of the relation between the interlocutors.

Homonymy and Seriality

Names that describe only a singular person (what in English one normally calls 'proper names' – but again this category cannot be too broadly generalized) can be used to reflect collective belonging either in a person-to-person manner or a person-to-group manner. In some contexts, it is permissible to 'invent' new names (as in urban Brazil); most often it is not. Even where that is the case, however, one very soon meets up with the boundaries of creativity. Proper names are usually chosen from among a relatively limited list or are created through the use of a set of relatively limited techniques, or both. What this means is that homonymy is a recurrent aspect of most naming systems. People are often given names that belonged to other people before them (often relatives, patrons, godparents, etc.). Namesakes have relations between them, which are often quite intense (Pina-Cabral, João de, 2010b). They can be created in a number of ways, so it can be that people 'own' a series of valued names and, in the course of life, they pass these onto younger persons (Maybury-Lewis, 1974). Alternatively, people can receive the name of a dead relative (often a senior relative of the alternate generation – see McCallum, 2001 or Vernier, 1994) or they receive one of a rather limited list of names belonging to a family.

These forms of homonymy can reach paroxysms of repetitiveness, as was often the case in the so-called Celtic Fringe of Europe (from northern Portugal, along the Atlantic coast, to Scotland – see Dorian, 1970). Cases of generalized homonymy, however, should not be read as mistakes or as, somehow, signs of ignorance – as is so often taken for granted by ethnographers who study such contexts. Rather, name repetition must be seen as a perfectly legitimate (albeit statistical and not mechanical) mode of constructing collective belonging (Zonabend, 1984; Segalen, 1980).

People's names often respond to and reflect their particular social roles, as classically explained by Boas for the original populations of British Columbia that he studied (Boas, 1897). But there are also a large number of examples of this in Africa and Asia. The passing on of names between persons of different generations is often accompanied by the transfer of specific responsibilities and by the experience of constitutive surrogacy between the persons involved in the name transmission. In fact, it is generally the case that, even when there is no homonymy strictly speaking, the namer and the named experience a specifically strong relation of copresence (Pina-Cabral, João de, 2010b).

Homonymy and name seriality are somewhat continuous as processes. Very often people are 'named after' someone else merely by means of the linking of the names through a particle. Thus, for example, the initial letter of the name or an aspect of the name is kept on in the name of the younger named person, thus signaling social linking across generations.

This same process can be used to create commonality among members of one single generation. In upper-class Qing China, proper names of males were usually composed of two particles, the first of which was common to a series of brothers or patrilateral cousins (Alleton, 1993). This kind of seriality can also be found in contemporary Brazil and it was known to have occurred in some lower-class French populations (Wateau, 1989).

Naming and Life Course

Within each particular sociocultural context, persons typically follow a broadly recognizable life course. They are prone to change status at different moments in the life course and very often this change corresponds to recognized changes in naming. Such changes are often experienced as sudden, ritualized moments rather than as continuous evolutions. Ethnographers and historians have noted that these processes of personal change are not approached as binary breaks (on/off) but rather as rites of passage – that is, tripartite processes where the principles that effect the break are outlined by the nature of their absence during a liminary or intermediate stage.

One of the most common aspects of personal naming throughout the world is that a child seldom receives a definitive name until the immediate period of danger after birth has passed. In many contexts, recently born children are referred to by means of subterfuge or by offensive or descriptive names. The fear that the child might not be able to resist the forces of evil that confront a fully formed human was reflected in a number of naming practices. Ritual naming (as in baptism or other kinds of initiation rituals), however, usually occurs quite early on in the life of a person. Later on, successive life stages are often marked out by rituals, which characteristically involve name change; either through the actual change of name, or through the accumulation of names, or yet through the attribution of titles or other linguistic markers of distinction.

People may change certain parts of their names only (as in the case of French and British women, who often change surname at marriage – or, alternatively, in the case of monks, who change their proper names upon taking orders) or they can hoard valuable names that they carry with them and redistribute at a later moment. Life course rituals continue well into death and beyond in many instances, so funerary naming is very common. Of course, in historical contexts where Christianity has played a long-term role that is not the case. Since the sixth century, when Christian theories concerning the

spiritual essence of humans became more definitive, the soul is seen as created at conception and to continue forever (Givens, 2010). This means that baptism is conceived as a definitive change in a person's soul, a spiritual rebirth. To that extent, funerary names, which are so common elsewhere, do not make sense in Christian contexts.

The relation between naming and the essence of personhood – what anthropologists often call 'soul' – is very porous. Name magic is very commonly found, both for obtaining positive and negative effects. Indeed, this is the most common root of the widespread practices of name silencing and restriction of use (Parkin, 1989). While personal names cannot in principle be fully private, the fact is that a person's name is seen as somehow continuous with a person's value, so nowhere can names be used in an absurd or irresponsible way without that having implications for the bearer. In many contexts known to ethnographers, the European presupposition that formal names are essentially public does not apply. People may avoid declaring their name, they may not appreciate being called out aloud, they may feel their name is too precious a thing to be used lightly (Ramos, 1995). It must be understood, however, that the silencing of names is always a relative matter, not the same as the withdrawal of a name from the process of sociality.

There are, however, contexts where some people are not subject to direct naming. This may be a mark of subalternity, as used to be the case with Cantonese women (Watson, 1986). But it may also be a mark of distinction. Often, certain people are barred from pronouncing the name of certain other people (relatives, affines, friends, or hierarchical superiors), thus marking the specific nature of their relation by means of the negation of processes of naming that are taken for granted in other relations. Still again, rules of etiquette can limit considerably the way some people can use other people's names. In Imperial Qing China, for example, characters that were part of the Emperor's name were banned from general use for so long as he remained alive.

Conclusion

In the course of writing these pages I have been obliged to overuse words such as 'typically,' 'characteristically,' 'often,' 'may,' 'generally,' 'frequently.' While this may worry some readers for it may seem vague, the fact is we have no option but to learn to live with that kind of open-endedness in anthropological comparison and analysis. If, indeed, human communication is only possible within what Quine and Davidson called interpretive indeterminacy, and since sociality is essentially a communicative process, we have to accept that nothing will ever be absolute, complete or fully determinable in human experience (Davidson, 2005: 211). Thus, a condition for speaking of human life in its broadest outlines is to accept to remain open-ended. The alternative of giving up on broad generalization is as dependent on a dystopia of positive knowledge, as the alternative of believing in the possibility of formulating universalities is dependent on a utopia of positive knowledge. Both have proved equally insufficient for anthropological analysis. There is no margin for doubt that the deethnocentrification process that generations of ethnographers have patiently undertaken has left us with an invaluable legacy of information concerning the human condition in its more general outlines. But indeterminacy and underdetermination will never vanish, that is, history will ever be our condition – both in science and in everyday life. This, however, should not mean that we have failed to learn the great lessons inscribed in our anthropological and historical record.

Nanotechnology: Social and Cultural Aspects

Brigitte Nerlich and Szczepan Lemańczyk, University of Nottingham, Nottingham, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Nanotechnology is not just an emerging technology but also an emerging cultural phenomenon. From its earliest beginnings nanotechnology and nanoculture have lived in a symbiotic relation, one inspiring the other. Promises and hopes, fears and doubts about nanotechnology have found expression in movies, novels, video games and so on. Nanotechnology and art have inspired each other. In this context public perceptions of nanotechnology have emerged, evolved, and been studied by social scientists. This discussion provides an overview of both the intertwining of nanotechnology and culture and of some of the public perceptions that may have been shaped by this process.

Introduction

The sociologist C. Wright Mills wrote in 1959:

> [I]n their everyday life they [men] do not experience a world of solid fact; their experience itself is selected by stereotyped meanings and shaped by ready-made interpretations. Their images of the world, and of themselves, are given to them by crowds of witnesses they have never met and shall never meet. Yet for every man these images – provided by strangers and dead men – are the very basis of his life as a human being.
>
> (from Alexander, 2009, p. 11)

Nanotechnology involves studying and working with matter on an ultrasmall scale: one nanometer (nm) is one-millionth of a millimeter, or one-billionth of a meter; a single human hair is around 80 000 nm in width. Nanotechnology deals with the creation and use of functional materials, devices, and systems with novel functions and promises to lead to improvements in microelectronics, energy technology, biomedicines, and more. Nanotechnology has a long history as a science and technology, but it only began to penetrate the sociocultural sphere in earnest around the turn of the second millennium. Public perceptions of this emerging technology are shaped by ready-made interpretations and images, as nanoscale phenomena are well beyond the range of what the human eye can see and as promising applications are still mostly in the future.

Stories and images are therefore important to embed this new technology in society and for society to be able to absorb, appreciate, contest, and engage with it. In the following section, we first provide a short cultural history of nanotechnology. This is followed by an overview of how cultural narratives and culturally salient images are used to construct perceptions and visions of nanotechnology. We then go on to sketch various attempts made by social scientists to assess public opinions and perceptions of nanotechnology, and finally we attempt to determine how public opinion may be shaped by the media, as a mediator between science and society and one of the main distributors of 'ready-made interpretations.'

A Short Sociocultural History of Nanoscience/Nanotechnology

Standard histories of nanoscience/nanotechnology typically begin by referring to Richard Feynman's famous 1959 lecture "There's Plenty of Room at the Bottom" (Feynman, 1959). In this afterdinner speech, Feynman, physicist and Nobel Laureate, sketched the possibility of manipulating and controlling matter on a small scale, indeed down to the bottom of the atomic scale. This mention of Feynman's talk is usually followed by a reference to K. Eric Drexler, who, in his 1986 book *Engines of Creation: The Coming Era of Nanotechnology*, speculated not only about controlling matter at the atomic scale but also about molecular assemblers that could potentially self-replicate endlessly, a dystopian scenario that could lead to what he called *gray goo* (Drexler, 1986). Drexler later regretted the use of this phrase, as it was employed in the initial phase of 'nano hype,' around 2004, as a way to induce fear rather than to portray nanotechnology as a revolutionary technology of hope and promise (Bensaude-Vincent, 2004).

Sometimes histories of nanotechnology refer to other events before and after Feynman (Regis, 1996), such as Norio Taniguchi using the term *nanotechnology* in a 1974 paper on ion-sputter machining; Drexler using the concept of molecular nanotechnology at the Massachusetts Institute of Technology in 1977; the first publication of a technical paper on molecular engineering and the invention of the scanning tunneling microscope in 1981; the discovery of the buckyball (C60) molecule, a first nanomaterial, in 1985, and the invention of the atomic force microscope in 1986.

A few years later, in 1989, Don Eigler of IBM Almaden and his colleagues used a scanning tunneling microscope (a microscope that sees through touch, so to speak, to spell out the IBM logo using xenon atoms, an image that put nanotechnology on the map of the public imagination (Eigler and Schwiezer, 1990)), and was followed by even more spectacular images of 'quantum corrals' that became icons of science and at the same time *objets d'art*. This was the beginning of a period of give and take between advances in nanoscience and advances in societal speculations about these advances, including a host of science fiction scenarios explored in popular culture (Nerlich, 2005).

In 2000, Bill Clinton, then president of the United States, launched the US National Nanotech Initiative, and serious financial investment began to pour into the development of nanotechnology. In 2003, US Congressional hearings were held and many surveys, opinion polls, and public engagement and outreach activities were launched on the societal implications of nanotechnology. In 2004, a landmark report by the U.K.'s Royal Society and Royal Academy of Engineering was published under the title Nanoscience and Nanotechnologies: Opportunities and Uncertainties (Royal Society and Royal Academy of Engineering, 2004).

Nanotechnology began to attract the attention of social scientists, who started to study public perceptions (Shapira et al., 2009), to engage the general public with nanotechnology and to reflect on its cultural significance, especially with relation to topics such as art and science, science and fiction, and science and literature – titles of three sections of one of the first books devoted to nano culture (Hayles, 2004).

Nano Facts Meet Nano Fictions

In this context of increasing social science scrutiny, the story or myth of Feynman as the founding father of nanotechnology was challenged by the cultural anthropologist Chris Toumey (Toumey, 2008), who told a more convincing story about the beginnings of nanotechnology. Furthermore, the idea that Feynman was the first to talk about manipulating matter at the atomic sale was challenged by Colin Milburn, an expert in science and the humanities (Milburn, 2008). He traced the idea back to the science fiction writer Robert Heinlein and his novella *Waldo* (see Milburn, 2008). Having come across both Toumey's and Milburn's work, the physicist Richard Jones pointed out on his blog *Soft machines*:

> There's no evidence that Feynman had read "Waldo" himself, but Feynman's friend Al Hibbs certainly had. Hibbs worked at Caltech's Jet Propulsion Laboratory, and he had been so taken by Heinlein's idea of robot hands as a tool for space exploration that he wrote up a patent application for it (dated 8 February 1958). Ed Regis, in his book *Nano* (1996), tells the story, and makes the connection to Feynman, quoting Hibbs as follows: "It was in this period, December 1958 to January 1959, that I talked it over with Feynman. Our conversations went beyond my 'remote manipulator' into the notion of making things smaller … I suggested a miniature surgeon robot …. He was delighted with the notion"
> (Jones, 2010).

In "Plenty of Room at the Bottom" Feynman (1959) did indeed talk about 'hundreds of tiny hands' and also about 'swallowing tiny surgeons.' Both images, whether related to Heinlein/Feynman or not, would flourish in fictional accounts of miniaturization and in semifictional accounts of nanoscience, and we shall come back to their enduring attraction in the next section. Here is what Feynman said in his talk about swallowing surgeons:

> A friend of mine (Albert R. Hibbs) suggests a very interesting possibility for relatively small machines. He says that, although it is a very wild idea, it would be interesting in surgery if you could swallow the surgeon. You put the mechanical surgeon inside the blood vessel and it goes into the heart and 'looks' around. (Of course the information has to be fed out.) It finds out which valve is the faulty one and takes a little knife and slices it out. Other small machines might be permanently incorporated in the body to assist some inadequately-functioning organ.
> (Feynman, 1959, p. 30)

A first quasi-scientific image (an artistic and imaginative rendering) of such a small machine appeared in 1988 on the cover of *Scientific American*: "A nanomachine swimming through a capillary attacks a fat deposit (such as normally may accompany an arteriosclerotic lesion)" (Nerlich, 2005). Coincidentally this was a year after the movie *Inner Space* was screened, which was itself a parody of the 1966 movie *Fantastic Voyage*, which became an enduring trope within nanoscientific and popular nanotechnology discourses (Nerlich, 2005, 2008). In *Fantastic Voyage* a submarine and its crew, including a surgeon, is shrunk to microscopic size and injected into the blood stream.

As late as 2010 one could still read pronouncements such as this: "'We are all motivated toward realizing the vision of the 1966 movie 'Fantastic Voyage' and by the potential to enhance medical treatment' Wang tells Nanowerk" (Berger, 2010). *Fantastic Voyage* is such an enduring trope that even those who want to provide more 'realistic' insights into the workings of nanotechnology in general and nanomedicine in particular end up replicating some of its aspects, as for example in an introduction to nanoscience for kids called *Nanoreisen* (nano voyages) (http://www.nanoreisen.com/; also see *Nanomission* at www.fei.com/resources/nano-games.aspx).

There has always been a singularly close relationship in nanotechnology between science and culture, images and imagination, and facts and fictions, with facts inspiring fictions and fictions inspiring facts (Goodsell, 2009). And, we should not forget that technologies, such as various types of advanced microscopes, are being used to do science and also to produce art (see a yearly nano art exhibition at http://nanoart21.org/).

But what does it mean to produce images of (invisible) nanoscale phenomena or images that popularize nanoscience dealing with nanoscale phenomena? And how do these images work? Most importantly, such images have to be able to tell a story. As Gimzewski and Vesna pointed out:

> In both the philosophical and visual sense, 'seeing is believing' does not apply to nanotechnology, for there is nothing even remotely visible to create proof of existence. … More than in any other science, visualization and creation of a narrative becomes necessary to describe what is sensed, not seen …. The scale becomes too abstract in relation to human experience.
> (Gimzewski and Vesna, 2003, p. 3)

In the following section we shall see how nanoscale phenomena are both made visible and used to create visions of the future.

Images Meet Visions

Nanotechnology deals with phenomena that are invisible to the human eye; they are indeed below the wavelength of light

(Goodsell, 2006, p. 44). This poses problems to image visualization. In addition, many applications of nanoscience still lie very much in the future. This opens up a space for the creation of futuristic visions, both utopian and dystopian ones. This in turn has implications for public acceptance or rejection of this new technology, as well as for attracting funding and investment.

The technological problem of making the invisible visible was solved with the invention of the scanning tunneling microscope and other microscopes of a similar type. The problem of public perception – of bringing nanoscience and its applications to the attention of the general public – was first overcome through the creation of images that make the unfamiliar familiar. As early as 1987 Bruno Latour had written about this issue:

> You feel bad because the nanometers of living cells baffle your mind? But it means nothing for anyone as long as it baffles the mind. It begins to mean something when nanometers are centimeters long on the scaled-up electron photograph of the cell, that is, when the eye sees it at the familiar scale and distance. Nothing is unfamiliar, gigantic or far away in these centers that cumulate traces; quite the opposite, they cumulate so many traces so that everything can become familiar, finite, nearby, and handy. (Latour, 1987, p. 230)

Philosophers of nano returned to this topic more recently in 2011:

> The nano-world is not a fantasy world, nor is it an urban, technical, or cosmic world. Instead we encounter for the most part a domesticated nature that is unsettled but not wild … We are drawn into a world in which we are used to move around that looks manageable and waits to be colonized.
> (Schwarz and Nordmann, 2011, p. 234)

The first to make the invisible visible and the unfamiliar familiar was, as we have seen, Eigler with the creation of the IBM logo written in xenon atoms. At the time this was a very laborious process, a process that has now become so commonplace. But, as Roald Hoffman wrote: "Raw electronic images have no color, only intensity among shades of gray. Wavelength information (color) may be communicated later … Immediately, in the choice of color(s), hue and intensity, one is led to artistic decisions" (Hoffmann, 2007, p. 20). And as Eigler himself, the creator of beautiful 'quantum corrals,' pointed out:

> The orange corral was something that I did specifically for the cover of *Science*. I wanted to create an image with as dramatic a perspective as possible to entice the editors into using the image on the cover of the magazine. I chose the colors, 'lighting conditions' and point of view of the observer to suit the purpose of the moment. … When Dominique Brodbeck created the blue corral image, we had a more educational or scientific purpose in mind, and so the perspective is one in which you get a much better idea of the shape of the corral and the shape of the waves in the interior of the corral. Nonetheless, Dominique's image appeared on the cover of *Physics Today* (November 1993).
> (quoted in Frankel, 2005, p. 263)

In the creation of these and many other nano images, science and culture, technology and art merge in a variety of combinations, depending on the cultural context in which they are used and on the communicative intention behind the merger. Artistic conventions of landscape painting or the painting of fictional scenarios can influence the representation of fact, as when coloring quantum corrals, perhaps in the tradition of magazines such as *Astounding Science Fiction* (Hoffmann, 2007), but fiction can also go it alone and create images of future nanomachines that do not yet exist.

As we have seen, fictional visions and images of nanoscience have been circulating in the discourse of science fiction for a long time. They can be used to shape public perceptions to create hopes or fears; they are producers of nano visions. Some of the most important images and fictions relating to nanoscience are those of 'swallowing the surgeon,' which, as noted earlier, were indicated by Feynman and linked to films such as *Fantastic Voyage* and its various sequels and caricatures (Nerlich, 2005). Here we have an image of hope related to nano medicine and expressed in language and imagery related to 'fighting' disease, a common way of speaking about health and illness (Nerlich, 2012). In this context nanobots are conceptualized and visualized as delivering drugs and healing people. One of the most important incarnations of such a nanobot is the so-called nano-louse, which has been variously studied by social scientists (Nerlich, 2008; Ruivenkamp and Rip, 2010), an artistic, but unrealistic rendering of a medical nanomachine in the tradition of the 1988 one that appeared on the cover of *Scientific American*. This image is however still being used in 2013, for example, in a promissory article on nano medicine (Kainic, 2013), which ends by saying, "[a]s Martel notes in an article in IEEE Magazine, 'There is no shortage of possibilities … a real-life fantastic voyage is just beginning.'"

However, there is also a darker side to nanobots, exploited in stories about 'gray goo' or self-replicating nanobots or nanites, perhaps best incarnated in Michael Crichton's novel *Prey*, published in 2002 just before a surge in public attention to nanotechnology. Nanites also have made their appearance in many other novels, movies and video games and have become a particular vehicle for public perceptions and visions of nanotechnology (Milburn, 2008). These types of images, utopian ones and dystopian ones, as well as merely playful ones, continuously serve to science-fictionalize science fact and blur the boundaries between cultural visions and scientific reality.

Images of nanobots not only switch between portraying promise or peril, they also switch, more regularly, between the biological and the mechanical, especially when nanoscientists talk about not-yet-existing but soon-to-exist nanomachines as if they were as real as the (metaphorical) motors, machines, propellers, pumps, gears, or scaffolds that already float through our bodies in the shape of enzymes, cell membranes, or parts of bacteria – as Lang and Gerber (2009, p. 24) call it, "a template orchestrated by nature." Here nanotechnology is made to appear normal by being seen through the lens of nature and the natural.

Images of flowers and landscapes in particular are often used to illustrate texts on nanotechnology. One of the most iconic nano flowers is the blue flower created by scientists in Cambridge in 2004. A BBC news item pointed out at the time that "the nano-sized plants are 'grown' from tiny droplets of the

liquid form of the metal gallium on a silicon surface" (BBC News, 2004). These flowers and landscapes make the unfamiliar seem familiar. This is also true of the use of nano-size cars or guitars or maps or any object than can be 'drawn' using advanced microscopy instruments, including in 2008, a 'Nanobama' (www.nanobama.com/).

Some of these construction and visualization efforts are linked to the metaphor of the 'master builder,' an over-arching metaphor that has been explored in detail by López (2008). Building the world atom by atom was in effect the title of a 1999 brochure produced by the National Science and Technology Council, whose front cover paints an image of an atomic landscape against a backdrop of space, thereby mapping the mappings of space exploration onto the exploration of the newly discovered nano space (Birkeland and Strand, 2009).

Images of nanoscale objects and the visions of nanotechnology that they convey are still being produced today and have become ubiquitous online, especially in image competitions and image galleries, as well as nano-art galleries that function as hybrid spaces between art, culture, and science (de Ridder-Vignone and Lynch, 2012).

Public Perceptions of, and Attitudes toward, Nanoscience and Nanotechnology

Alongside an ever-expanding and changing creation of cultural images and narratives around nanotechnology in science and in popular culture, there has been an increasing flow of studies into how nanotechnology is perceived when the general public is exposed to such images and visions, whether through traditional and online media or through reading novels or by playing video games (Alvardo, 2012). We return to media coverage of nanotechnology in the next section. In this section we provide a short survey of social science research into public perceptions and attitudes.

Social scientists and humanities scholars began to pay attention to nanotechnology around 2003/2004, after the congressional hearings in the United States and the publication of a Royal Society/Academy of Engineering report that emphasized the need to take account of potential public resistance to nanotechnology (Roco and Bainbridge, 2005). The Economic and Social Research Council (ESRC) in the United Kingdom said at the time that "nanotech looks set to become the next big showdown between science and society" (ESRC Social Science Week, 06/04, quoted in Nerlich et al., 2007, pp. 159–160).

In this context, many countries, especially the United States and the United Kingdom, invested heavily in public engagement with nanotechnology activities, and policy makers began to talk about 'upstream engagement' (Rogers-Hayden and Pidgeon, 2007). The hope was that if nanotechnology was publicly discussed openly and early, there would be a better chance of avoiding the so-called GM debacle, namely the full-scale rejection of a technology, genetically modified food in this case, by great parts of the general public.

Social scientists tried to establish a baseline for public understanding (or rather various aspects of public understanding) of nanotechnology that could then be used to engage sections of the general public more effectively with nanotechnology. Surveys focused in particular on differences between public perceptions in different countries (Gaskell et al., 2005), as such differences in perception that contributed to differences in accepting GM in Europe and the United States. They also compared the views of people holding different religious beliefs, for example, because such beliefs or values might impinge on differences in perception and uptake (Toumey, 2011).

Many studies have shown that (at least in the initial phase of nano awareness, and to some extent, nano hype) public attitudes toward nanotechnology have mostly been positive, especially in the United States (Scheufele and Lewenstein, 2005). Gaskell et al. (2005) point out significant differences in the way nanotechnology is perceived in the United States and European countries, with Europeans being more conscious about the potential nano risks. This research into public perceptions continues and is becoming more sophisticated.

It is generally assumed that some of the knowledge about nanotechnology that such surveys assess is derived from the mass media (Scheufele and Lewenstein, 2005). The media are one of the main purveyors of social and cultural knowledge and shape it in various ways through a process called 'framing' (based on the strategic use of words and images).

Nanotechnology in the Media

Where little direct experience of issues exists, the media play an important role in creating perceptions of such issues, and this is especially the case for nanotechnology, which is only gradually penetrating ordinary people's lives. This gradual penetration is of two kinds. On the one hand, mundane applications of nanotechnology are becoming commonplace but mainly go unnoticed. Such applications include the use of nanoparticles in self-cleaning windows or antibacterial socks; one can call such uses 'normal nano.' On the other hand, there is what one may call 'the nano-fantastic' described in films, novels, and video games. In such situations, where there is quite a gap between the mundane and the fantastic, the media play an even more important role in shaping public perceptions and attitudes. Anderson et al. state that "the press play a potentially crucial role in framing newly emerging issues, mainly by helping to establish the initial parameters of debate, by identifying certain news sources as pertinent and credible, and by providing topic-defining reference points" (Anderson et al., 2005, p. 202). Therefore, studies of the media coverage of nanotechnology have increasingly attracted the interest of social scientists and scholars in media studies (see, for example, Friedman and Egolf, 2005; Stephens, 2005; Anderson et al., 2005). In a study of media coverage of nanotechnology in German newspapers, Zimmer et al. (2008) suggest that discussions about nanotechnology are still in an initial phase and, unlike biotechnology, nanotechnology has not yet been a subject of many concerns, i.e., there is no 'Dolly the sheep' publicity or 'Frankenfood' campaign in connection with nanotechnology, despite some anxieties around toxicity, ground water pollution, penetration

of cell walls by nanoparticles, etc. It seems that so far the 'avoid the GM debacle' strategy has worked.

The Social and Cultural Framing of Nanotechnology

Framing is a way to organize a story or an idea (especially a new one) in such a way as to make it comprehensible to those who are so far unaware of it. Frames are sense-making tools (Scheufele and Tewksbury, 2007). According to a widely quoted definition (very often used in other framing studies) offered by Gamson and Modigliani, a frame is the "central organizing idea or story line that provides meaning to an unfolding strip of events …. The frame suggests what the controversy is about, the essence of the issue" (Gamson and Modigliani, 1987, p. 143). Traditional and online media are public spaces in which frames are created, used, and disseminated. This means that "media frames might help set the terms of the debate among citizens, but rarely, if ever, do they exclusively determine public opinion. Instead, as part of a 'frame contest,' one interpretative package might gain influence because it resonates with popular culture or a series of events, fits with media routines or practices, and/or is heavily sponsored by elites" (Nisbet and Scheufele, 2009, p. 1770).

A number of frames have been used to raise awareness of nanotechnology, to discuss its benefits and risks (Donk et al., 2012; Lewenstein et al., 2005), and just to enjoy the fun of its novelty. Frames can be signaled, triggered, or established through a variety of 'framing devices,' including metaphors (master builder, revolution), images (nanobots, nano flowers, etc.), stock myths and legends (Prometheus, Pandora's box), stock literary characters (Frankenstein, Dr Moreau, Waldo), or stock literary book or movie titles (*Brave New World, Fantastic Voyage*), stock historical references (asbestos, thalidomide), and clichés (playing God, going down the slippery slope, be careful what you wish for). Such literary devices can have positive or negative connotations; for example, a book that provides a dystopian vision of the future can be uncoupled from the original vision and later provide a positive framing, as mostly is the case when websites and headlines talk about the brave new world of nanotechnology.

The choice of frames is therefore important and has been discussed extensively, for example, by the European Commission in a brochure entitled "Understanding Public Debate on Nanotechnologies: Options for Framing Public Policy" (European Commission, 2010).

However, despite the deluge of work on social and cultural aspects of nanotechnology, only a small proportion of that research is devoted to examining media framings of attitudes toward and public perceptions of nanotechnology in non-Western cultures. There are some exceptions (for an overview, see Lemańczyk, 2012), but more work needs to be done, as, nanotechnology as a cultural phenomenon will be influenced by the cultural context in which it develops.

Conclusion

From its very beginning nanotechnology has not only been a scientific and technological phenomenon but also a social and cultural one. Artists have been inspired by advances in nanotechnology to produce new forms of art; novelists and film and video game makers have incorporated ideas derived from nanotechnology to engage readers, viewers, and players with new forms of science and new forms of fiction. Nanoscientists themselves have, conversely, been inspired by art to produce nanotechnology-based artifacts, ranging from letters to logos to flowers and landscapes. This almost continuous give-and-take between fact and fiction, hype and reality was at its height between 2002 and 2004. This is when Richard Jones wrote, "There is an almost surreal gap between what the technology is believed to promise and what it actually delivers" (Jones, 2004). Over the past decade this gap has become narrower. There are now numerous products on the market that contain nanoparticles, from sunscreens to trousers to (increasingly controversial) food. Nanotechnology has become part of reality. However, nanotechnology is also still a fertile ground for popular imagination, fiction, and speculation. It is therefore all around us in our everyday lives and in our everyday imaginations. We shall have to wait and see whether the issue of nano food for example might still become a GM moment in the development of nanotechnology and which cultural resources might be mobilized if it does.

Narrative Approaches to Organizations

Hervé Corvellec, Lund University, Lund, Sweden

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article presents an overview of the narratives in and about organizations. It is structured as follows. The first section introduces the idea that organizational members are *Homo Narrans* or storytelling beings; the second section describes the tenets of narrative enquiry in organizational settings; and the third section discusses the pros and cons of storytelling, which is the systematic use of narratives to manage people.

The notion of narrative does not only refer to novels, films, and other works of fiction. Narrative refers instead to any way of representing a series of events as a sequence that moves from a beginning point to an ending point. These events can be real or imagined, and they can pertain to anything that one has in mind, for example, nature, artifacts, or human activities. There exists an almost infinite diversity of narrative forms, for example, formal or mundane, oral or written, in dance, or in paintings. Narratives can be produced, circulated, and received in private or in public, individually or in a group. They can also serve a wide range of purposes, including incentivizing people to go to work. Narratives crowd politics, news reporting, and scientific theories, as well as sport commentaries, directions about how to get somewhere, and accounts of one's day at the office. There is no group of people without a narrative activity and tradition; narratives are present in every age, in every place, and in every society.

Organizations are no exceptions. Through their budgets, strategic plans, and annual reports to project meetings and wage discussions, narratives pervade organizations. These narratives are essential to organizational life, and studying how organizational narratives are produced, circulated, and received proves to be a fruitful way to study this life.

Part 1: Narrative Anthropology: Organizational Members as *Homo Narrans*

Narratives are essential to how humans create a sense of time for themselves (Ricœur, 1984). By ordering events chronologically, narratives provide this sense of time. Narratives can expand time. For example, a brief announcement of a Chief Executive Officer's (CEO) dismissal can be described in such a wealth of detail about the atmosphere and the attitudes of the people present that it takes a longer clock-time to read this description than it took for the Chairman of the Board to read the announcement. Inversely, narratives can compress time, for example, when an account of the event states that "It took a few weeks for the Board to find another CEO." Thanks to narratives, humans can actually relate to the mechanical clock-time and create an intelligibility of their lived times, that is time as they experience it in their lives.

The ability of narrative to make sense of time is closely connected to the ability of narrative to create a sense of causality. This latter ability is conveyed by the notion of plot. Aristotle defines in the *Poetics* a plot as an arrangement of events into a whole with a beginning, middle, and end. More precisely, a plot expresses how one passes from one state of affairs to another state of affairs that is different. By so doing, a plot provides a sense of progression, coherence, and understandability. For example: "The disclosure that the CEO had lied about having a PhD led to his immediate dismissal by the Chairman of the Board. However, the historical role of the CEO in the past developments of the company and major disagreements among the shareholders about the future orientations of the corporation made it difficult to find someone to replace him. It took a few weeks for the Board to find another CEO." A narrative's plot organizes one's understanding of how the past conditions the present and influences the future. This is particularly true of masterplots: plots that, because they have been told over and over, have acquired a moral force. For example, how the young David could defeat Goliath thanks to strategically directed efforts serves regularly as evidence that skill can prove to be superior to force.

Providing a sense of time and causality, narratives help people make sense of the negotiated order of organizational life. Organizing is akin to plotting (Czarniawska, 1997), and managers are the practical authors (Cunliffe, 2001) of their experience of an organization's life. Narratives have proven to be of practical help not only in making sense of organizational events, introducing change, and gaining political advantage (Boje, 1991), but also in identifying hazards, defining risk, and ascribing blame (Gephart, 1993). Even the celebrated process of drafting corporate strategies proves to be an ad hoc, conflictual, and multivoiced process of negotiating convincing narratives (Barry and Elmes, 1997). Managers expend consequential effort in selecting facts and ordering them into plots to produce a legitimate discourse that can orient their actions (Abolafia, 2010). Alone or with others, managers draw on all of the heroic, tragic, romantic, or ironic narrative styles to orient themselves and others in the ambiguous, changing, and open-ended everyday of organizational life.

The reason is that humans are in their actions and practice essentially storytelling animals (MacIntyre, 1981). Human communication rests on narration, and humans are *Homo Narrans* who depend on narratives to produce and communicate their interpretations of the world (Fisher,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.73118-7

1987). The capacity of humans to engage in collective actions is not limited to a logico-scientific mode of thought (Bruner, 1986): a mode of thought that rests on an ideal of a formal (mathematical) system of description and explanation, on categorization or conceptualization that follows a formal logic of conjunction, disjunction, implication, and aims at providing explanations in terms of causes and consequences that strive toward generalization. Rather, the capacity of humans to build and develop organizations rests as much on a narrative mode of thought (Bruner, 1986): a mode of thought that emphasizes the roles of good stories, gripping dramas, and believable historical accounts; that intends to address the vicissitudes of human or human-like intentions and actions, and more generally human experience; that works through contextualization; and that also emphasizes the singular.

Narratives are building stones of individual and organizational identity constructions. The history of a company posted on its Website is nothing but a selection of events that the current top management team wants the people inside and outside the organization to consider as characteristics of the company. Likewise, a job application emphasizes which past experiences and future expectations the applicant considers as most likely to be relevant to an advertised position. In both cases, it is a matter of building an identity through narration in the sense of defining the narrating subject with the help of a coherent and purposeful sequence of events in the past, present, and future. Organizational gossip and un-told stories function in the same way: they select and emphasize.

"We have evolved from being a waste management company to being an energy company" or "I am project manager with a proven focus on both people and results": such narratives help organizational members answer the existential questions of who they are, why they work, who they can trust, why they should say yes or no, and the like. Narratives are technologies of the self (Tamboukou, 2008) that provide ways for organizational members to work out their sense of organizational and professional identity. Correspondingly, narratives help nonorganizational members elucidate what kind of people and/or organization they are dealing with, and thus help them make sense of their and other people's identities as consumers. Narrative approaches to organizations link up with the thesis that humans realize the meaning of their life through narration (Arendt, 1958). Narration is the characteristic feature of the human condition in that it makes it possible for humans to go beyond a mere biological expression of life (*zôé*) and express a unique human ability not only to act, but also to give meaning to our actions by reflecting and communicating about them (*bios*).

By acknowledging the importance of narrative knowledge for interpretation, communication, and action, organization studies plug into the vast cultural heritage of storytelling. In particular, a narrative approach to organizations makes it possible to "gain access to deeper organizational realities, closely linked to their members' experiences" (Gabriel, 2000: p. 2). An interest in organizational narratives makes it possible for organization studies to (re-)connect to fundamental anthropological aspects of organizing that might otherwise remain ignored, such as the pervasiveness of fantasy in organizational settings as well other aspects such as humor or derision, complacency or contempt, even conflicts and violence. Organization members keep telling narratives to communicate and keep consuming narratives to make sense of their world. It is thus important to develop methodological ways to track and analyze the production and circulation of narratives in organizations. This is the object of organizational narrative enquiry.

Part 2: Narrative Enquiry: Ways of Studying Organizations

Narrative enquiry is not a cohesive field. Ways to collect and analyze narratives are as diverse as narratives are numberless. Narrative enquiry stands for a broad spectrum of fieldwork and reading methods, some of which will be introduced in this section.

Organizational narratives are often transmitted orally, in small talk at coffee breaks or on the job to help solve a task, and they include gossip, rumors, and jokes (Orr, 1996). Many of these narratives are not necessarily yet stabilized, realized, and articulated; they are prospective sensemaking, a kind of narrative bet on the future, and therefore Boje (2001, 2008) calls them antenarratives. Told and retold, antenarratives can become organizational narratives and even corporate legends that act as weaker versions of antique myths (Gabriel, 2000). An example of such a legend is the oft recounted anecdote that Ingvar Kamprad, the billionaire founder and CEO of the Swedish furniture company IKEA, once stopped and chatted with two of his executives sitting in business class in the front part of a plane while he was on his way toward the rear part of the plane to sit in economy class: this narrative perfectly serves IKEA's corporate policy of cost saving out of every detail and Kamprad's image of an ordinary, on the edge of stingy, self-made man. However, many organizational narratives are also put into print, like the CEO's letter to the shareholders, advertising, or job announcements. One can even collect written narratives by providing an arbitrary starting point and, with surprisingly good results, then asking managers to fill in with a narrative (Kostera, 2005).

Collecting written narratives is potentially less challenging, methodologically speaking, than collecting oral narratives as the latter often need to be elicited. Interviews and shadowing are efficient ways to collect narratives since many respondents provide accounts that are spontaneously formed into narrative. One can also prompt narratives by asking "can you recall when you first started to talk about the necessity of reorganizing your department? And what happened next?" (Czarniawska, 2004: p. 51); finally, working with the interview transcript, one can concoct one's own narrative out of what the respondents have said.

The rationale of organizational narrative enquiry is to consider that narration underlies organizing (Czarniawska, 1997), then look for narratives – for example, stories about reforms and change, life and identity, or failures and drama – and, finally, read the material that has been collected as narratives. Classical narratology (Herman and Vervaeck, 2005; Prince, 1982) offers a conceptual framework to analyze the formal characteristics of a narrative. These are the kinds of questions that narratology asks: Who tells the story

(narrator)? To whom is the story told (narratee)? Is the author the same as the narrator or is the story told from a point of view different from that of the author? What is the plot of the narrative? How is time rendered in this plot, and how does this affect the readability of the plot? How are the characters and the settings described? Classic narratology, which is strongly influenced by structuralism, tends to isolate the text from its social context. It focuses on the text's formal aspects, and this can be seen as a limiting trait to its use. Postmodern narratology tries to release narratology from this limitation, for example, coupling narratology to feminist studies, which opens new passageways for organization studies.

In contradistinction to techniques focused on the formal aspects of narratives, other narrative enquiry techniques provide ways to study narratives in their organizational context and help to understand this context. Boje (2001) lists eight such techniques. (1) Deconstruction unfolds the ideological assumptions that underlie a narrative, for example, which voices it privileges or silences. (2) Grand narrative analysis relates the narrative at hand to the metanarratives that characterize a specific society at one time in history, for example, the metanarrative of progress in modernity or that of incredulity in postmodernity. (3) Microstoria analysis looks at the other end of the macro–micro continuum and investigates how a narrative refers to knowledge and events that are very specific to a given time and given place. Microstoria often privileges narratives produced by the 'little people.' (4) Story network analysis aims at mapping, for example, with network diagrams, how a narrative relates to other narratives and how these relations follow or differ from the contact patterns among people or among organizations, and, more generally, the social networks within which organizational actors evolve. (5) Intertextuality analysis shares with story network analysis an interest in how narratives relate to one another, but focuses on how a narrative borrows or distances itself from other narratives, for example, through loans or quotations. (6) Causality analysis focuses on the kind of causes that are invoked to put together the fragments that constitute the narrative, for example physical, psychological, or successionist causality. (7) Also focused on causality, plot analysis focuses instead on how a narrative unfolds the arrangement of events in the text and then relates this arrangement to the four master forms of emplotment: romance, satire, comedy, and tragedy. (8) Finally, theme analysis uncovers how stories make sense of the chaotic everyday of organizational life by bringing events into known themes, for example, bureaucracy. Together, these ways of reading a narrative provide an understanding for how narratives function in the social settings where they are produced, diffused, and received.

Within all these accounts, narrative enquiry offers a rich method to analyze organizational culture. Methods inspired by narratology or other methods of narrative enquiry provide a practical means to critically examine taken-for-granted assumptions and analyze how organizational members and nonmembers perceive and use organizational rituals and symbols. Such methods also unfold the rationales of practices that are specific to the organization. More generally, narrative enquiry provides insights about how organizational members enact and reenact organizational culture.

Organizational scholars with an interest in narrative have also shown the relevance of works of fiction for management practice, management studies, and management education. A key rationale behind the use of works of fiction for the study, teaching, and practice of management is to get closer to the subjective experience of organizational membership (Phillips, 1995). Managers are invited to read good novels – and one could also watch good films – to become better managers (Czarniawska and de Monthoux, 1994) following the argument that works of fiction provide rich case studies that transmit tacit knowledge and render the complex dynamics of organizational life without simplifying it. For example, the classic play *Antigone* offers an opportunity to get public administrators into a discussion of the ethical dimensions of law enforcement (Marini, 1992); a bestselling textbook, *The Goal*, written in the form of a novel in the classic master–teacher–pupil genre, can effectively teach accounting techniques; and *Dilbert* (e.g., Adams, 1997) demonstrates the relevance of humorous narratives to convene, and possibly help support, the absurdities of office life. Paying attention to novels, films, TV series, and other narrative expressions of popular culture provides, moreover, an opportunity for managers and management scholars to reflect on how management is perceived by the public at large.

Part 3: Narrative Leadership: Storytelling in Organizations

The potential that exists in using narrative for a practical managerial purpose has not gone unnoticed by management consultants and other supporters of managers. In a few years, storytelling has established itself as a standard managerial tool. Armstrong (1992) is one of the earliest advocates of storytelling as a managerial tool. 'Storying around,' as he says, is simple – you have done it since childhood. Stories are timeless – old stories will prove as effective as new ones, and they are demographic-proof – everybody likes to listen to them. Stories are memorable, and they are therefore an excellent way to pass along traditions, an efficient form of training, and a wonderful form of recognition. Stories are also a great way to recruit and hire people; moreover, they even work to sell products. For Armstrong, storytelling is simply an effective way to make you a better manager.

There seems to be a story, type of story, or way of telling stories for every managerial situation, purpose, and style. Fables are praised for coming with a moral, sagas with a hero, and detective stories with a clarification. Storytelling is featured as a privileged way to communicate, inspire, mediate knowledge, build trust, support people, overcome problems, and bring along change – in two words: practice leadership. Storytelling is also invoked to turn the history of a company or a product into a good story that conveys an identity, a sense of time and place and values – a story easy to remember. This story can be an embellishment of the past, such as when leaders at the Walt Disney Corporation systematically invoke the genius (or genie?) of Walter Disney (Boje, 1995). But the story can also be faked, such as when two Swedish restaurant designers invent Joe Farelli, a successful restaurant owner from Little Italy in New York

City, to establish the credibility of an eponym mafia-films pitched restaurant in Gothenburg. "Let me tell you a story…" is featured as an all-round managerial tool.

This tool is not innocuous, though. Stories format brains and thoughts as much as they inform; and it is hard to have reservations about narratives since one of their key traits is to deflect questioning, bracket criticism, and neutralize critique. Storytelling is an efficient tool for corporate power: it creates a dream society that facilitates a corporate control on mental representations; a clever plotting has an ability to conceal logical contradictions and lock people in contradictory binds able to destructure work collectives; the depiction of actual persons as larger than life creates unrealistic patterns of explanation and expectations; a steady repetition of success stories establishes performance levels as standards that are basically unrealistic, thereby creating a permanent sense of shortfalls and failure among the workforce; and, puns and derisive stories can turn not only oppositions but even injustice and suffering into mockery (Salmon, 2010). Simple plots and streamlined organizational histories simplify the diversity of organizational life and legitimate ad hoc rewards and punishments (Corvellec, 1997). Storytelling harnesses the age-long art of telling stories to create a fictive work environment but uses this fiction to run real work places in the interest of the storyteller.

Conclusion

The growing returns of narrative anthropology, enquiry, and politics have prompted a vivid interest among organizational practitioners, scholars, and students for narratives from, in, about, and around organizations. This interest has allowed major advances, for example, in understanding how organizational members use links of causality when they provide accounts, the role of temporality in organizing, and, more generally, the richness of organizational members' experiences. Novels, film, and other narrative forms have a proven pedagogical record. Moreover, storytelling has grown into a managerial tool aimed at creating a sense of organizational history, developing the cohesiveness of organizational culture or supporting organizational change.

However, this success raises a corresponding need to develop a critical awareness about narratives in organizations. The point of such a critical awareness is not to reject a narrative mode of thinking, enquiring, and leading in favor of reverting to a mode of understanding organization that would rest exclusively on what Bruner (1986) calls a logico-scientific mode of thought. The narrative mode of thought offers unique epistemological and practical entries into the reality of organizational life, and it would be a real pity to ignore the benefits that it can bring. But at the same time, the use of narratives as a mode of enquiry, a way to present organizational research, or a management tool should be accompanied by a good dose of critical awareness. There are limits to the capacity of narrative to represent things (Kohler Riessman, 1993). A critical sense is needed to explore these limits, and, for example, identify the political agenda, values and priorities, and the worldview that any narrative perpetuates. Narratives can be so seductive that it is difficult to question how they connect the past, present, and future, and what they claim about how people get along. Critical awareness is what is needed to resist the seductive power of narratives.

Narrative Exposure Therapy

Maggie Schauer, Clinical Psychology, University of Konstanz & vivo international, Konstanz, Germany

Abstract

Narrative Exposure Therapy (NET; Schauer, Neuner, Elbert 2005/2011) is an evidence-based treatment for trauma spectrum disorders in adult and child survivors of multiple stressors with complex trauma histories. NET was originally developed to treat survivors of war, terror, torture, and abuse. Since oral narratives are an integral part of every human culture worldwide, and imaginal exposure is proven to be a first-line treatment in trauma spectrum disorders, NET ensures healing of trauma symptoms through these components. The testimony approach that is inherent in this treatment enables the survivors to reclaim their life stories and also assists societal repair. Based on these principles, it has been shown that individuals from diverse backgrounds with a high trauma load and broken lifelines, suffering from traumatic stress, significantly benefit from NET. Working through an individual's biography facilitates recognition of the interrelated emotional networks of experiences in cases of multiple, repeated, or continuous trauma and hardship. This helps to build episodic memory and contextual indexing, fosters a sense of identity, and gives deep personal understanding of schemas and social emotions that have evolved across the lifespan. Revisiting and processing socially painful situations whilst supported by active, empathic listening allows for a corrective and healing relationship experience and integration. Subsequently disturbing symptoms significantly decline and the overall health and immune functions as well as social and occupational functionality increase. In Narrative Exposure work survivors can find meaning, testify to human rights violations, regain dignity, and satisfy the need for acknowledgment and validation.

Theoretical Underpinnings for Narrative Exposure Therapy

As humanitarians, we aim at alleviating the plight of war and complex emergencies, of natural and manmade disasters, assisting human beings who experience human-/child-rights violations, abuse, and continuous trauma. When one stressful experience after another adds to the growing associative memory of fear and trauma, the feeling of threat becomes a permanent plight. Given the high prevalence of emotional neglect, and familial, sexual, and organized violence that is not limited to geographic regions shaken by war and crisis but can be found in all countries of the world, low-threshold trauma treatments are needed to overcome these 'building blocks' of traumatic events and allow remembrance. In search for straightforward, disseminable approaches that are not linked to formal education, culture, or age, field-based studies have shown the efficacy of this short-term, evidence-based trauma treatment method, Narrative Exposure Therapy (NET), which can be successfully implemented on a large-scale level and applied by locally trained lay counselors (Schauer et al., 2011; Jacob et al., 2014; Neuner et al., 2004b; Schauer and Schauer, 2010). To heal individuals and communities it is essential to conduct and evaluate trauma treatments in real-world settings and to respond to universal human psychosocial needs (Nickerson et al., 2011; Robjant and Fazel, 2010).

Typically, the construction of an individual's reality involves a dimension of historicization and localization in the continuum of past, present, and future (Schauer and Ruf-Leuschner, 2014). Survivors of trauma, however, often encounter difficulty detailing a biographical account consistent in both content and sequence (Elbert and Schauer, 2002; Ehlers and Clark, 2000). In severe and complex cases, entire lifetime periods can seemingly be lost. Traumatized people fail to sufficiently connect their impulses, bodily sensations, and experiences to the contexts of their biography (Schauer et al., 2005/2011). Individuals who suffer from chronic trauma spectrum disorders have typically been exposed to multiple traumatic stressors such as assaults and persecution in their community or repeated incidences of familial violence including abuse, neglect, and social rejection. Effects are most devastating when the child had to endure repetitive and prolonged stress during development (Elbert and Schauer, 2014; Ruf and Schauer, 2012; Teicher et al., 2006).

As a consequence of their trauma memory, survivors suffer from a range of painful symptoms, leading to severe problems in daily functioning and participation in social life. Symptom remission and achieving functionality requires traumatic experiences to be oriented in the appropriate context, particularly the time and place, in the autobiography, i.e., trauma-focused remembering. Forcing a survivor to simultaneously recall, rank, and prioritize some traumatic events over others in order to participate in an 'exposure exercise' is often not only technically impossible but can even hinge on unethical. The process of having an individual select the 'worst' traumatic event from their trauma history oversimplifies the intricate context surrounding each event and neglects to address developmental influences. However, a viable treatment option that circumvents such complications and is both efficient and effective involves the narrating of the *entire* life story in a manageable period of time. The steady, step-by-step working through an individual's biography facilitates the recognition of interrelated emotional networks of experiences. The aim of NET is to complete the survivor's autobiography by linking *hot* (sensory–bodily–emotional) and *cold* (episodic) memory traces of events, thus contextualizing the experience of major traumata. Narrative Exposure builds on the theory of the dual representation of traumatic memories (Brewin et al., 2010; Elbert and Schauer, 2002; Schauer et al., 2011).

During a traumatic event, mainly sensory and perceptual information is stored in memory. The mind and body become

extremely aroused (rapid heartbeat, sweating, trembling) and brace for actions such as opposing or escaping. Emotional memories are tied together in a network of sensory, cognitive, emotional, and physiological elements. The sensory elements, together with the related cognitive, emotional, and physiological responses, then form associations in memory related to the traumatic experiences (*hot memory*; Metcalfe and Jacobs, 1996; *situationally accessible memory, or sensory perceptual representation*, see Brewin et al., 2010; Schauer et al., 2011). These hot memories are disconnected from the contextual information that constitutes the *cold memory* (*verbally accessible memory*, or *contextual representation*), i.e., the individual cannot remember the event within their contexts, i.e., where and when they have happened. Environmental stimuli and internal cues can easily activate the trauma structure. Multiple trauma is conceptualized as an extension of the fear/trauma network through experience of multiple traumatic events in such a manner that the fear network becomes increasingly strengthened and enlarged and ultimately can be triggered by exposure to a wide range of cues contained associated with the network.

Since the activation of the fear/trauma network serves as a frightening and painful recollection, many patients learn to avoid cues that act as reminders of the traumatic event and are unable to orient the specific fear associated with the events appropriately in time and space or to clearly structure these traumatic events in chronological order (Schauer et al., 2011). Trauma networks connect to response dispositions, which can either be an alarm response with fight and flight behavior or dissociative responding (fright, flag, and faint: e.g., functional sensory de-afferentation, emotional detachment, and numbing while tonic or flaccid immobile). Thus, dissociative amnesia or 'shut-down' can occur, replacing intrusions and hyperarousal with dissociation and passive avoidance (for a more detailed understanding of the biology of surviving and the defense cascade see Schauer and Elbert, 2010). NET is thought to reverse these detrimental conditions by tying down connections to their exact context.

As adversities and stressors cumulate, the trauma network expands, ultimately leading to clinically significant trauma-related suffering. There is a dose–response relationship ('building block') between experiences of traumatic events and trauma spectrum disorders. All symptoms of traumatic stress disorders and depression have repeatedly been shown to correlate in their severity with the cumulative exposure to traumatic stress (Mollica et al., 1998; Schauer et al., 2003; Neuner et al., 2004a; Elbert et al., 2009; Schauer E. and Elbert, 2010). More recently, it has become obvious that childhood adversity is the other major dimension in predicting trauma-related mental illness (Catani et al., 2009, Neuner et al., 2006; Teicher et al., 2003).

We all carry numerous implicit associative neural networks that have formed in response to emotionally arousing experiences, with many never reaching conscious awareness. Therein, mutually excitatory mnemonic representations are interconnected with action dispositions (emotions) and behavioral and physiological responses. Salient discrimination between past and present, between what are memories and what are current sensations, is essential. A well-tolerable way to attain this is working through both the negative and the positive life events chronologically, furnishing a narration about the entire biography. Reorganizing the memory and embedding the traumatic events in one's stream of life, in their appropriate positions on an individual's biographical timeline can achieve acknowledgment and closure of painful experiences. Revisiting positive, resourceful moments and taking the time to explicitly examine them one by one helps empower the individual to be able to look forward to the future (for both see Schauer et al., 2011).

In NET, the individual, with the assistance of the therapist, constructs a chronological narrative of his or her life story with a focus on the traumatic experiences. Fragmented reports of the traumatic experiences will be transformed into a coherent narrative. Empathic understanding, active listening, congruency, unconditional positive regard, and directive perseverance are key components of the therapist's approach for individuals under continuous trauma conditions, after familial, sexual, and organized violence, emotional neglect, or social relational victimization. For traumatic stress experiences the therapist asks in detail for context, emotions, cognitions, sensory information, physiological responses, and probes for respective observations. The narrator is encouraged to relive these emotions while actively maintaining their connection to the 'here and now': using permanent reminders that the feelings and physiological responses result from memories, the therapist links the experiences to episodic facts, i.e., time and place. In this way reprocessing, meaning making, and integration are facilitated. At the end of treatment the documented autobiography may be used for human rights advocacy.

The therapeutic procedure of NET (see **Figure 1**; *for a detailed account of the structure of NET, see the* treatment manual by Schauer *et al.,* (2011); for a clinicians short description see Elbert et al., 2015)

- Part 1 (duration: 1–2 sessions, each about 90–120 min): Structured clinical interview of trauma spectrum disorders including event checklists followed by a brief psychoeducational introduction (trauma memory, symptoms, outline of the treatment rationale and plan, approximate number of sessions)
- Part 2 is optional (duration: 1 session, 90–120 min): Laying out the *Lifeline* as a biographical overview
- Part 3 (duration: about 4–12 sessions, each 90–120 min): *Narrative Exposure* as the core procedure of NET, narrating the life story in several treatment sessions along the chronology of the timeline with an emphasis on high arousing moments, focusing on the reprocessing of traumatic experiences by inviting 'imaginal exposure'.

The Character of NET

To heal individuals and communities NET was tested in ecologically valid, various real-world settings, i.e., in scenarios of conflict and crisis as well as in typical inpatient and outpatient clinical settings (Schauer et al., 2004; Onyut et al., 2004, 2005; Neuner et al., 2004b, 2008a; Bichescu et al., 2007; Maedl et al., 2010; Neuner et al., 2011; Crombach and Elbert, 2014; Pabst et al., 2015; Hensel-Dittmann et al., 2011; Robjant and Fazel, 2010). NET was found to be a robust, low-threshold approach that is not linked to formal education, culture, or age. Field-based studies have shown the disseminability and

Part 1 Diagnostics	Part 2 Lifeline	Part 3 Narrative Exposure	
Diagnostic interview including event checklists + **Psychoeducation**	**Laying out the lifeline** symbolizing highly arousing, important events	• Narration **starts** at the beginning of life, proceeding along the lifeline. Traumatic events are confronted and reprocessed (**imaginal exposure**) until arousal decreases. Notes of key points are taken. • **Between sessions:** therapists structures the own transcript, writes the narration down and takes it to the next session. • In the **following session** in sensu exposure is facilitated again through the rereading of the last part of the narration with active participation of the survivor. Narration gets corrected and more details are added. • The **procedure is repeated across sessions along the timeline,** highlighting important life-events and summarizing others, until a final version of the client's biography is reached.	Closing session: **re-reading** the entire narration *or* portraying a **final lifeline** Survivor and all witnesses (therapist, interpreter, co-therapist) **ritually sign the testimony**. Document is **handed over** to the survivor. Utilization for **human rights work** or juridical purpose is discussed.

Figure 1 The Narrative Exposure process (Schauer, M., Neuner, F., Elbert T., 2011. Narrative Exposure Therapy: A Short Term Treatment for Traumatic Stress Disorders, second ed. Hogrefe Publishing, Cambridge, MA.).

efficacy of this short-term, trauma-focused treatment module that can be successfully built into large-scale service provision and applied by, e.g., trained counselors, psychologists and psychiatrists, medics, paramedics, social workers, and teachers (Schauer, E. 2008; Neuner et al., 2008b; Jacob et al., 2014). Because narratives are an integral part of every culture, people from diverse backgrounds with broken lifelines suffering from stress caused by events such as, e.g., sexual and physical childhood abuse, forced recruitment or migration, political violence and torture, life-threatening illnesses, disasters, or victimization by peers and attachment figures can benefit from the building of episodic memory and the facilitation of their testimony. NET has a therapeutic and human rights focus.

Therapeutic elements of NET that have proven effective in trauma treatment (from Schauer et al., 2005/2011)

1. Active chronological reconstruction of the autobiographical/episodic memory.
2. Imaginal exposure to the traumatic events ('hot spots') and full activation of the fear memory in order to modify the emotional network through detailed narration and imagination of the traumatic events.
3. Meaningful linkage and integration of physiological, sensory, cognitive, and emotional responses to one's time, space, and life context (i.e., comprehension of the original context of acquisition and the reemergence of the conditioned responses in later life).
4. Cognitive reevaluation of behavior and patterns (i.e., cognitive distortions, automatic thoughts, beliefs, responses), as well as reinterpretation of the meaning – content through reprocessing of negative, fearful, and traumatic events – completion and closure.
5. Revisiting of positive life-experiences to activate resources and to adjust basic assumptions.
6. Regaining of the survivor's dignity through satisfaction of the need for acknowledgment through the explicit human rights orientation of 'testifying.'

For full information about the NET procedure, see the treatment manual:

Schauer, M., Neuner, F., Elbert, T., 2011. Narrative Exposure Therapy: A Short-Term Treatment For Traumatic Stress Disorders, second ed. Hogrefe Publishing, Cambridge, MA.

In addition to the English edition, there is currently a Japanese, French, Korean, Slovak, and Italian version of the treatment manual as well as a Dutch interpretation (see references).

Evidence for NET

Adult and child survivors with multiple traumatizing life-events have been demonstrated to benefit from NET. State-of-the-art *in sensu* exposure and the narrative reprocessing of the trauma memory, the broken lifeline, and ultimately the entire biography effectively reduces suffering and allows the survivor

to foster personal identity (Jongedijk, 2014; Robjant and Fazel, 2010; Dömen et al., 2012). Individuals from diverse backgrounds with lives torn apart by stressful events like childhood abuse and neglect, loss of caregivers, adoption, forced recruitment or migration, political violence and torture, life-threatening illnesses, severe disasters, and many more show significantly reduced clinical symptomatology and an enhanced quality of life and level of occupational and social functioning (Mørkved et al., 2014; Hermenau et al., 2013; Dyregrov and Yule, 2006). NET therefore also provides effective treatment for survivors of organized violence and severe torture experiences with large effect sizes (Hensel-Dittmann et al., 2011; Neuner et al., 2010) or complex trauma survivors, including those with borderline personality disorders (Pabst et al., 2012a,b, in press). Stenmark et al. (2013) showed that with NET, refugees as well as asylum seekers can be successfully treated for post-traumatic stress disorder (PTSD) and depression in a general psychiatric health-care system. Most pronounced improvements are observed at (long-time) follow-up, suggesting that NET elicits an ongoing change in the dynamics of self-perception and self-regulation of the client, commencing a healing process that eventually leads to a sustained improvement in psychopathological symptoms, physical health, functioning, and quality of life. NET has effectively been applied in situations that remain volatile and insecure, like conditions of continuous trauma, i.e., ongoing real threat, e.g., by war or by a perpetrator (Neuner et al., 2014). It effectively reduces PTSD symptoms in the individual whilst bearing witness to the atrocities endured. Reviews identified NET as an evidence-based treatment for different groups of survivors of violence (Robjant and Fazel, 2010; Crumlish and O'Rourke, 2010; McPherson, 2012; Nickerson et al., 2011). Meanwhile, a number of studies showing the effectiveness of NET have been conducted completely independent from the originators of NET (Zang et al., 2013; Hijazi, 2012; Hijazi et al., 2014; Gwozdziewycz and Mehl-Madrona, 2013; Ejiri et al., 2012; Dōmen et al., 2012) and thus the NET procedure has been successfully implemented in a variety of countries (e.g., Zech and Vandenbussche, 2010; Jongedijk, 2012, 2014). NET is available in special adaptations for offenders (FORNET; Elbert et al., 2012; Hermenau et al., 2013; Crombach and Elbert, 2014) and for children and adolescents (KIDNET; Schauer et al., 2005, 2004/2011; Onyut et al., 2005; Catani et al., 2009; Ruf et al., 2010; Hermenau et al., 2012; Neuner et al., 2008a; Ruf and Schauer, 2012).

The effectiveness of NET has been demonstrated not only by measuring the clinical and social symptoms but also in validating these results by means of markers from neurophysiology and molecular biology. NET as a successful psychotherapeutic intervention can reorganize the memory and modify the architecture of the brain on a macroscopic level (Schauer et al., 2007, 2006). The success not only showed up in symptom scores but also in parameters of neuromagnetic activity. During the 6-month follow-up oscillatory brain activity in the NET group, but not in the control group, became more similar to that of healthy controls. Moreover, using magnetic source imaging of the brain, Adenauer et al. (2011) observed that NET causes enhanced cortical top-down regulation, which is associated with the ability to inhibit the fear response.

Various somatic diseases, including chronic pain, cancer, cardiovascular, respiratory, gastrointestinal, and autoimmune diseases (Boscarino, 2004; Seng et al., 2006; Felitti et al., 1998), emerge from traumatizing experiences. Altered immune functions and inflammatory processes are found to be responsible for the poor physical health in individuals with PTSD (Pace and Heim, 2011). NET was shown to turn health parameters (like frequencies of cough, diarrhea, and fever) for the better even under harsh living conditions (Neuner et al., 2008b). In the immune system, T-cells are critical for maintaining balance, regulating the immune response, and preventing autoimmune diseases. Recently, Morath et al. (2014) showed a treatment-related increase in the previously decreased proportion of regulatory T-cells in the NET group at 1-year follow-up. Moreover, NET is able to reverse in individuals with PTSD the pathological levels of DNA strand breaks back to a normal level (Morath et al., 2014b). These findings may have implications for physical health, including carcinogenesis.

A decisive strength of NET is its encouragingly low drop-out rate and, due to its robust nature, the potential for dissemination, including to counselors in low-income countries, war, and crisis regions (Schauer and Schauer, 2010; Catani et al., 2009; Neuner et al., 2008b; Ertl et al., 2011; Jacob et al., 2014).

Narrative in Social Work

Christopher Hall, Durham University, Durham, UK

Abstract

The 'narrative turn' has had a major impact across the social sciences, but has been slow to develop in social work research. This article outlines some of the major approaches to narrative theory and analysis in the social sciences, looking at narrative structure, identity, and performance in talk and interaction. Empirical research, which deploys narrative approaches to examine social work topics and narrative analysis is applied to research interviews, texts and everyday social work talk and interaction are identified. Implications for social work practice are also indicated.

Introduction

Narrative is intrinsic to social work. Stories are told to social workers by service users (Hall et al., 2006; Hyden and Overlien, 2005; Marvasti, 2002). Social workers tell stories to other professionals (Crepeau, 2000; White, 2002; Riemann, 2005) and write stories in files (Hall, 1997; Hall et al., 2006; White et al., 2009). Stories are told by service users and social workers to researchers (Hall, 1997; Martin, 1998; Wells, 2010). Narrative is increasingly featured in social work education (Rutten et al., 2010). Social workers are encouraged to think of their practice in narrative ways (Baldwin, 2013), with specific social work methods drawing on narrative (Parton and O'Byrne, 2000). Social work has a strong oral tradition (White, 2002) and social work agencies might be seen as 'storytelling organizations' (Boje, 1991). This article will examine what the study of narrative and storytelling can offer social work theory and practice.

While narrative theory and analysis has traditionally been associated with literary studies, over the last 30 years theory, research and practice drawing on narrative have flourished across the social sciences. Narrative approaches to data collection and analysis are now a constituent part of (mainly) qualitative research methods, some directly applying concepts from literary theory to talk and interaction in a wide variety of contexts. Many aspects of social life draw on, are constrained by, or constituted through narrative. Indeed, some authors (both literary and social science) suggest that it is our ability to make sense of our social world through storytelling, which makes us human. Roquentin says in Sartre's novel *La nausée* (1938: 64):

> 'a man is always a teller of tales, he lives surrounded by his stories and the stories of others, he sees everything that happens to him through them; and he tries to live his own life as if he were telling a story'.

Social psychologists, Gubrium and Holstein (1998: 163) suggest that "more and more, we are learning that life comes to us in the form of stories", and Jameson (1981: 13), a political scientist, talks of 'the all-informing process of narrative which I take to be the central function or instance of the human mind'.

However, the 'narrative turn' in the social sciences has been so far-reaching that writers discuss narrative from different and sometimes contradictory positions. These include: identifying narratives in everyday talk and interaction (e.g., Sacks, 1992); seeing narrative as located in the psychology of the individual 'the storied self' (e.g., McAdams, 1996); viewing narrative as a feature of wider community formations (e.g., Rappaport, 1995); and focusing the analysis on the text itself (e.g., Labov, 1972). While offering a wide range of possibilities for the researcher, it is often hard to compare writers' different theoretical foundations. Furthermore, the popularity of narrative has resulted in publications in which any form of talk that recounts past events, especially interview data, is referred to as a narrative, even when no narrative analysis is attempted (Atkinson, 1997; Riessman, 2008).

This article concentrates on how narrative contributes to social work, particularly research concerned with narrative structure, identity, and performance. First, I outline some of the key features of narrative theory, followed by a discussion of how data for narrative research analysis are collected and analyzed. I give particular consideration to narrative research that examines social work topics. Finally, I examine how narrative helps us better understand the users of social work and social work practices.

Definitions of Narrative

Although different disciplines emphasize different aspects, there are some commonalities. Narrative suggests a temporal aspect to talking, writing, and thinking usually with a beginning, middle, and end. Events are organized in such a way that the resulting narrative has consequences for both the narrator and listener/reader. It implies a move from one state of affairs to another, and in doing so, makes a point. Furthermore, the telling of the story is an occasion in which the narrator and listener attempt to communicate and make sense of their social world. As Riessman and Quinney (2005: 394) put it, "sequence and consequence: events are selected, organized, connected and evaluated as meaningful for a particular audience."

Some writers distinguish between narrative and story, especially in literary theory. In terms of etymology, narrative is

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28059-8

associated with an authoritative telling of events, whereas storytelling is associated with entertaining an audience, setting up an interesting challenge for the audience as to the truthfulness or deception of the story. In the social sciences, the use of these terms is less precise. Johnstone (2001: 639) makes the distinction between narrative as talk about a sequence of events, and story as the act of storytelling, whereas Linde (1993), in contrast sees narrative as a subunit of a person's life story. In this article, I use the terms interchangeably.

Narrative Theory

Some of the key concepts in narrative theory are time, identity and performance and are associated with the philosopher, Paul Ricoeur, although it is not suggested that all narrative research directly flows from his work. Ezzy (1998: 246) links the three concepts together in Ricouer's work:

> 'Narrative identity is coherent but fluid and changeable, historically grounded but 'fictively' reinterpreted, constructed by an individual but constructed in interaction and dialog with other people'.

Ricoeur develops the notion of time by examining the relationship between history and fiction; each draws on the other: "fiction is quasihistorical and history is quasifictive" (Ezzy, 1998: 243). When we recount the past, we inevitably draw on our interpretative imagination shaped by narrative. Ricoeur sees narrative as offering ways in which people make sense of events around them and turn those reflections into action: he asks, "in what way is the ordinary experience of time, borne by daily acting and suffering, refashioned by its passage through the grid of narrative" (1985: 249). The temporal characteristic of narrative is more than organizing past events. Storytellers give significance to those events for the present, which endure in ongoing narrative performances: "if we may speak of the temporal identity of a story, it must be characterized as something that endures and remains across that which passes and flows away" (Ricoeur, 1991: 22). Narrative provides structures for events to be interpreted and communicated. The key concept is 'emplotment': events that might appear unconnected, are taken from the teller's experience and synthesized into a unified and complete story. It is 'drawing configuration out of a succession' (Ricoeur, 1991: 22). Narrative theory influenced by structuralism, concentrates on the internal relations between the elements in the text (Propp, 1968). Ricoeur, however, takes a hermeneutic approach concerned with both the internal form and the lived experience of tellers and listeners.

For Ricoeur narrative enables us to gain a sense of ourselves, "life as an activity and passion in search of a narrative" (1991: 29). By creating and performing stories, we are able to create a coherent sense of who we are and at least for the time being we can create self-understanding, "Subjects recognize themselves in the stories they tell about themselves" (Ricoeur, 1988: 247). Narrative enables us to understand the world around us and also offers ways to act in and upon the world:

> 'Our life, when then embraced in a single glance, appears to us as the field of a constructive activity, borrowed from narrative understanding, by which we attempt to discover and not simply to impose from outside the *narrative identity which constitutes us*' (italics in original) (Ricoeur, 1991: 32).

Such an orientation has been developed by Bruner, "we have no other way to describing 'lived time' save in the form of narrative" (2004: 692). Bruner's work has been particularly important in narrative psychology and life story methods. He applies concepts from literary theory to distinguish three aspects of the story – theme, the main gist or moral of the story; discourse, the way it is told, in particular plot, language, and genre, the cultural conventions of storytelling. Bruner notes that not any story will do. To be successful, storytelling needs to draw on culturally available morals. It is the juxtaposing of (and most often resolving) these human dilemmas, what Bruner calls 'trouble' (2004: 697), which drives the drama of the story.

The third concept associated with narrative is performance, the story as told to an audience, and constructed in terms of 'ratified hearers' (Goffman, 1981). There is a tradition in literary theory for locating the understanding of the text in the interpretation of the reader (Iser, 1974), or as Fish (1980) calls it the 'interpretative community.' In the social sciences, the work of conversation analysts sees the story as constructed in the interaction between the teller and listener. When storytelling is examined in everyday conversation, the formal features of narrative are harder to identify. Edwards (1997) challenges attempts by Bruner and others to identify definitive elements of a narrative. As Goodwin and Heritage (1990: 299) say: "Rather than treating stories as self-contained cultural artifacts, conversation analysts have stressed the way stories are structured with respect to the contingencies of the interaction in which they are embedded."

Sacks (1992) analyzed stories in conversation as one form of talk-in-interaction. A central feature of everyday conversation is its organization in terms of turn-taking; interlocutors generally manage sequences of talk in terms of, for example, questions and answers, invitation and acceptance/rejection. To make space to tell a story in ongoing talk, the storyteller creates an agreement to talk for an extended period without an interruption. This requires a 'story preface,' an announcement of an intention or request to tell a story, for example, 'I must tell you what happened to me the other day.' The listener is therefore constrained from interrupting until the story is completed, for example, with a closing comment like, 'so that's what happened.' The orientation is to study "how stories are told and what conversational actions are accomplished in their telling" (Stokoe and Edwards, 2006).

Collecting Narrative Data

When researchers carry out empirical research with a narrative orientation, the distinction between temporal structure, identity and performance characterizes the collection and analysis of data.

For some, the focus is how people talk about themselves and see the research act as a storytelling occasion, in particular life story approaches. Here, the researcher interviews the respondent and organizes the questions in such a way that story is encouraged, by, for example, asking about past events, with prompts 'what happened next.' In her study of infertility among women in India, Riessman (2008: 31) describes and analyzes interviews in which women describe how their infertility affected their personal history, relationships, and social status. The narrative is the whole interview, which is seen as coconstructed between interviewer and respondent.

Others assume that the respondent already has a story waiting to be heard which they have developed over time to make sense of their circumstances. This is especially the case in illness narratives (Hyden, 1997). For example, Mattieson and Stam (1995: 284) see stories about cancer as different from ordinary talk, "they are more than just 'stories' but the vehicle for making sense of, not an illness, but a life." Others see narrative analysis concerned to display hidden or silenced stories of oppressed or marginalized peoples. Again, their story is assumed to exist outside of the research process (Rappaport, 1995: 799).

Those with an interest in interaction see the narrative as one feature of talk or writing. Narrative is identified as displaying particular persuasive and performative features, as opposed to, for example, question and answer sequences or descriptions. The analysis concentrates on the interactional practices involved in producing a story and the consequences for the ongoing talk. Horton-Salway (2001) examines how people with chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) produce an accountable story of the onset of their condition, which is organized to resist versions that question it as a legitimate illness.

There are other versions of narrative. For example, shared narratives tell stories of a group or community, often sacred or mythical, which exist outside the individual or the interaction, but are available to be appropriated for personal identity and community interaction. For example, Humphreys (2000) examines narratives of Alcoholic Anonymous, which provides stories of hope as alternatives to dominant exclusion narratives. In summary, how researchers organize their data collection is strongly influenced by their definition of narrative – as ways of ordering the past, organizing a person's identity, or managing interactional dilemmas.

Narrative Analysis

In the analysis of narrative data, similar orientations apply. Researchers are interested in themes underlying the narrative, the structure of the story and their performance. Riessman (2008) identifies four approaches to analysis: thematic, structural, dialogic, and visual. Wells (2011) suggests narrative content, structure, and contexts.

Thematic

Analyzing the themes of what is said (or written) by respondents in a data corpus is the most widespread, but least distinctive approach to analysis. More traditional approaches to qualitative data analysis code: select themes that most represent the data; identify and compare instances across the data corpus. In contrast, narrative analysis is reluctant to break up the sequence of the narrative as each part is considered to be dependent on its location on the whole. In thematic approaches to narrative analysis, the researcher identifies themes in the way the respondents tell their story. As Riessman (2008: 53) says the analysis concentrates on "the case rather the component themes across the cases." For example, Dominelli et al. (2011) interviewed fathers involved in the child protection system. Their analysis produced a typology of different depictions of how the fathers described themselves, for example, 'misrepresented dad' or 'the mothering dad.' The analysis does not consider how the story is constructed or performed, but presents categories, which display overall themes regarding how fathers describe themselves in the interviews. Jansen and Haavind (2011) interviewed young people in residential care. They identified a distinction between stories characterized as 'If only' or 'Despite all.' They see such narratives as depicting the constraints of subjectivities, which are available in wider discourses to formulate their transition to adulthood.

Wells (2011: 44) considers thematic approaches are particularly appropriate for exploring social work issues, as they link respondents' talk to topics that social work might wish to explore. However, there is a danger that in analyzing narrative data as merely instances of self-evident themes, the complexity of narrative construction and performance is missed (Riessman, 2008: 76).

Structural

Structural approaches concentrate on how the narrative is organized, the form rather than the content. The influence of literary theory is evident with attempts to develop concepts like plot, character, genre, point of view in the analysis of talk and interaction. Narratives are considered to be organized in terms of beginning-middle-end. However, the key feature is how narrative is structured in such a way that it is consequential for the audience. The narrator needs to consider what aspects of the situation are included in the narrative and what are left out, and how the events fit into a plot, which the listener/reader can recognize. For the researcher, studying the underlying structures of the story can reveal the deeper meanings on which the narrator draws.

These approaches tend to concentrate on the narrative as a text, an artifact to be analyzed in itself rather than considering the narrator or storytelling occasion. The narrative is organized in such a way as to address an audience; sometimes specifically addressed and clearly identifiable; other times a general audience. In order to keep the audience involved, the narrative needs to address a number of tasks, for example, to make a point, be intelligible, not be repetitive, and have a sense of drama.

The most celebrated model for examining narrative structure is provided by the sociolinguist, Labov (1972). He was interested in how stories of African-American adolescents could be seen as having a coherent structure. He provides an ideal structure of a 'fully formed narrative,' based on the temporary organization of the clauses in the speech. There

are six elements: an abstract, which introduces the gist of the story to come; an orientation, which sets the scene; a complication, which introduces the problem or rupture in routine affairs; the evaluation, which indicates the significance of the event; the resolution, which deals with the problem and the coda, which rounds off the story. A verbal sequence of clauses in the story is matched to a sequence of events organized temporally. Such a structure provides both causality and credibility to the story, and is organized to counter what Labov calls the 'so what' question. The evaluation in particular is a direct address to the audience that events happened in the way they did and were (and are) important.

Riessman (2008) uses the Labovian model to understand how divorced people talk about relationship breakdown and make sense of their marital problems. She considers that the organization of events in the stories and the significance given to them uncover displays of distress which would not have been possible through thematic analysis. McDaniels (1995) examines how adults struggled to make sense of chaotic circumstances during their childhood by examining the use of various forms of evaluation in narratives to display the significance of events. Usita et al. (1998) uses narrative coherence to examine how people with Alzheimer's disease struggle to organize the chronology of their stories. In contrast to Labov, Gee (1991) provides a broader approach to examining narrative structure. He is concerned with identifying how parts or topics of long stretches of life story interviews fit together using the poetic feature of tone and voice, and displaying shifting temporal structures. His analysis identifies the narrative coherence in a life story told by woman suffering from schizophrenia, in what at first appears to be incoherent talk. Poindexter (2002) shows how different methods of addressing the structure of interview data (Labov, Gee, Mishler) uncovered different meanings. For example, by adding to Gee's model, a concern with the coconstruction aspects of the storytelling (for example, incomplete turns), more complex explanations emerge of the structure of the story, including affiliation between narrator and listener. Applying concepts of narrative structure provides important insights into how people describe and manage stressful situations by revealing the complexity of meanings on which narrators draw.

Performance

In contrast to studies of narrative structure, research on narrative performance concentrates on the telling of the story rather than the story itself. As Gubrium and Holstein (1998: 166) consider: "it casts storytelling as an ongoing process of composition rather than the more-or-less coherent reporting of experience." The evaluation clause in the Labov model implies an interruption in the temporality of the story to directly address the audience. Interactive approaches directly examine the ways in which stories are coconstructed, and their function in ongoing interaction. Storytelling is a practical activity produced for and with the listener to manage the dilemmas of the present encounter. Much of this work is concerned with narratives told in everyday situations, although the approach can also be applied to interview data by examining.

Everyday talk is likely to involve more complex methods of story preface and the negotiation of speaking turns. Conversational stories are rarely personal in the sense of belonging to a particular speaker or bounded by formal structures. Instead, they are coconstructed, contested and constituted in relationships, often characterized by challenges, questions, clarifications and speculations (Ochs and Capps, 2001; Crepeau, 2000). One story is often responded to with another story (Sacks, 1992) as the second narrator demonstrates his/her understanding of the significance of the first story. Likewise, the listener is likely to provide 'back-channeling' (Jefferson, 1984), comments like 'yeah' and 'mm' to encourage the storyteller to continue and responses of agreement or surprise at the denouement of the story. As Gubrium and Holstein (1998: 178) say "listeners are often active coparticipants in both the elicitation and production of stories, working with the machinery of ordinary conversation to shape storytelling."

Apart from negotiation of stories in turn-taking sequences, the storyteller is likely to include in the story features that may directly address the particular listener. These could be appeals to shared understanding of the salience of the story, 'you know what I mean?' They may also display their legitimacy to tell the story, the trusted teller of the tale (Shuman, 2006) by, for example, indicating their presence at the incident or expertise on the topic. Smith (1993) indicates how a student describes her friend's mental illness and provides preliminary instructions as how the story should be heard. For example, she states "I was the last to admit that she was becoming mentally ill," indicating that the mental illness was independent of her recognition, therefore, she was not complicit in its identification. Apart from addressing the potential 'so what' question, the storyteller faces a wide range of interactional challenges in terms of accountability, alignment and credibility, as in all communication (Buttny, 1993).

In institutional storytelling, the allocation of roles of narrator and listener are more likely to be established with particular kinds of stories following partially predetermined storylines. In counseling, welfare offices, medical consultations, stories are elicited with particular forms expected. In court, narratives are restricted in the sense that the storyteller is encouraged to tell the temporary flow of the events but prevented from indicating their significance. Gubrium and Holstein examine questioning by a district attorney of a potentially involuntary psychiatric patient. The district attorney starts a question-and-answer sequence, but then refuses to take the next allotting turn, thereby forcing the potential patient to extend and elaborate her story. As Gubrium and Holstein (1998: 177) summarize "narrative production is necessarily collaborative, even while it is institutionally informed."

Narrative in Social Work

This article has examined narrative theory and methods in general. We now look at research on social work topics, both the stories of service users and social work practices.

Riessman and Quinney (2005) carried out a literature review on narrative in social work and found four main

groups. The first and the majority of the papers were practice-oriented, specifically clinical. They were often case-based and explored how clients' stories were addressed therapeutically. There were also examples of self-narratives of client groups. However, they found that narrative theory was rarely applied to the analysis. The second group was narratives in pedagogy and how students write about their work. The third group was autobiographical accounts, particularly related to reflective approaches. The fourth group was research papers using narrative approaches. Overall the authors were disappointed in the research corpus, both the relatively small numbers and the lack of explorations of narrative theory and methods.

Despite the relative lack of significant exploration of narrative in social work research and theory, narrative can inform social work in a number of important ways. Versions of personal and social identity as constructed through narrative provide a major challenge to traditional notions of the individual in social work. Wilks (2005) provides a strong argument for the significance of narrative ethics, which resists the essentialism associated with social work views of people with fixed positions and definable characteristics. Narrative sees people as becoming and unfinalized and moral reasoning as 'narratively shaped.' It also challenges practices based on principles. He provides an example of 'choice.' In itself, the principle of choice for service users does not help to guide action if different stakeholders have different views of what is the right choice for the service user.

> '[In dilemmas of choice] … we are actually presented with are a series of intersecting stories about a situation. These stories look to both the future and the past, and offer competing outcomes based on different histories. We work with the stories, juxtaposing different accounts – the user's, the worker's, the manager's – looking for commonalities, points where the stories coincide, placing one story with another, the history and the outcome for an immediate choice played out within the larger narrative of a service user's life'
> (Wilks, 2005: 1256).

Interestingly, this contradicts Walsh (2009: 274) who suggests that 'the ultimate value of narrative practice is *empowering* clients' (italics in original). For Wilks (2005: 1260):

> '… the idea of moral sensibility [moves] away from the universalism of the categorical imperative or pursuit of the good life into a localized, temporal and changing sphere, much closer to our experience of the moral world'.

Understanding Clients

A number of researchers have investigated the narratives of the social work clients, using in-depth interviews to provide deeper understandings of the client. Wells (2011) analyses the story of a mother whose child was placed in care and then returned home. She examines how the mother constructs a narrative identity on the basis of the "fundamental binary opposition of the absent frightening mother versus the present protective mother" (p. 446). This study displays the complex and stigmatized identities with which mothers struggle, and are frequently suppressed by the child welfare system. Usita et al. (1998) found that people with Alzheimer's disease were often able to produce 'comprehensive and richly textured life stories' with the help of the research interviewer. They suggest that "it is conceivable that the salient events that were recalled, though limited, were enough to maintain some sense of self" (p. 194).

Martin (1998) describes a project in which young people leaving care were encouraged to tell their story, which the researcher typed (or 'scribed') in their presence. In a second session, they were encouraged to review and edit the story and then share it in a focus group with other participants. Such narrative construction highlighted the dynamic nature of narratives, not only producing a story but reflecting on it and having it questioned. Martin considers that in the process, the young people "found themselves in the telling, experienced themselves as creating themselves and as recovering themselves from the stories that had been told them" (p. 9). In mental illness, researchers examine the importance of narratives of psychotic patients to understand recovery. Roe and Davidson (2005: 94) suggest that narrative offers the opportunity to author "a new story. The process of authoring, in turn, helps consolidate and integrate a sense of self."

All these studies display the complexity of narrative and suggest that the study of narratives can lead to more sympathetic portrayals of social work service users. The view of shifting rather than fixed stories is of particular importance as it questions the requirements of social work systems to produce fixed versions of clients. Such an orientation links to studies of social work interaction in which versions of clients are seen as interactionally produced and managed (e.g., Hall et al., 2013).

Understanding Practices

Work gets done in social work by telling and evaluating stories. Service users approach social services agencies often with stories about their problems and how the agency can help. Marvasti (2002) examines how social workers in a homeless agency examine clients' accounts for their 'service-worthiness,' by editing the story in terms of the institution's mission. Urek (2005) also studies how social workers construct stories to produce a particular, characterization of clients to justify decisions and actions. She follows how a case is constructed and performed as a narrative in various meetings, and how it becomes the institutional narrative to establish the social services' version of the mother and child's character, which appears in a court report. Alternative narratives are undermined and disregarded.

Team and supervision meetings are particularly important occasions for the telling of stories. Pithouse and Atkinson (1988) examine how narrative enables the social worker to produce and justify the invisible craftwork of their trade to colleagues and supervisors. Riemann (2005) looks at social work case discussions and in particular the balance between narrative and argumentation. He notes how when social workers describe difficulties in making sense of their cases, the complexity of the stories are lost as colleagues narrow down the evaluation. Crepeau (2000) examines how narratives are told in multiprofessional meetings.

Professionals use stories of particular interactions with services users to evidence their portrayals to colleagues. How the story is told and how it is supported is crucial in informing subsequent decision-making. These studies examine the performance of the narratives in social work practices but make connections with institutional practices more generally.

Future Developments

Recent publications promote the exciting developments of narrative in social work (Larsson and Sjőblom, 2009; Wells, 2011; Baldwin, 2013). While the narrative turn has had a major impact across the social sciences, especially in medicine (Hyden, 1997), social work has yet to exploit the potential of narrative theory and analysis. For a profession concerned almost exclusively with talk and interaction, it is surprising that so little attention is paid to what happens in everyday social work (Hall and Slembrouck, 2009). Developing narrative approaches within practice intervention is particularly interesting. A range of approaches to narrative therapy have developed (White and Epston, 1990), some of which are applied to social work (Parton and O'Byrne, 2000; Roscoe et al., 2011).

There are, however, a number of criticisms of the popularity of narrative. Riessman (2008: 5) notes that 'narrative is everywhere but not everything is narrative.' Stokoe and Edwards (2006: 57) are particularly critical of biographical approaches, which they describe as "a contrived situation based on the assumption that their 'life stories' and experiences are readily available to 'dump' from memory." Atkinson (1997: 327) sees narrative research as a "mixed blessing … often sentimental and romantic," and warns against privileging the narrative as a special kind of representation. Woods (2011: 401) questions the instruction of the narrative researcher: "Tell us your story, because it is true (to the human condition), because it is yours (an authentic expression of your individual experience), and because it is good for you (as part of the healing process)."

Narrative Networks

Abstract

Narrative networks are a method for representing narrative data that facilitates systematic comparison and interpretation of qualitative accounts of social phenomena. The basic insight behind the narrative network approach is that it is possible to break a narrative into 'elements' and treat these elements as nodes in a network, where links between nodes represent either causal or temporal connection between nodes. Such networks can then be analyzed using standard network measures such as density, centrality, or connectivity. Sometimes the structure of the narrative network will be revelatory in and of itself – as in studies of identity formation – while in other cases narrative accounts can be compared or integrated.

Introduction

Over recent decades, social scientists have increasingly looked to narratives as a source of insight into social and historical processes. This 'narrative turn' (Polletta et al., 2011) has taken a variety of forms, but one important thread produced a series of strategies designed to systematically or formally represent the structure of narratives. Several of these approaches involve applying logical rules to a reduced or abstracted form of a narrative in order to reveal the underlying cause of an event (see Abell, 1987; Corsaro and Heise, 1990). In contrast, narrative networks are a method for representing narrative data that facilitates systematic comparison and interpretation of qualitative accounts of social phenomena. Rather than seeking to determine *why* something happened, the strength of the narrative networks approach is that it distills for the analyst *how the author of the narrative understood the event* (Gerteis, 2002). Sometimes this will be revelatory in and of itself – as in studies of identity formation – while in other cases narrative accounts can be compared or integrated, thereby revealing the extent to which multiple accounts mirror one another.

The basic idea behind the narrative network approach is that it is possible to break a narrative into 'elements' and treat these elements as nodes in a network, where links between nodes represent either causal or temporal connections between nodes. Such networks can then be analyzed using standard network measures such as density, centrality, or connectivity. Introduced in Bearman et al. (1999) and Bearman and Stovel (2000), the approach has been used to study a diverse range of substantive problems, including the local meaning of revolution and counter-revolution (Bearman et al., 1999), various types of personal life histories (Bearman and Stovel, 2000; Smith, 2007), the use of technology (Pentland and Feldman, 2007), and accounts of rape (Quinlan and Quinlan, 2010).

The narrative network approach extends a long tradition of using the lens of network analysis – with its focus on relational data and social structure – to analyze historical events from a social scientific perspective. The challenge of historical social science has always been moving beyond particularistic explanations while still retaining the salience of context. In response, scholars have used the narrative network approach to emphasize the function of particular types of events and produce comparable measures of the structural features of narrative, allowing for rich and systematic analysis of important social processes (Bearman et al., 1999: p. 509).

In the following article (Video Cultures: Television), we describe this approach, emphasizing narrative networks' dual status of theoretical orientation and methodological technique. First we briefly discuss the nature of narratives, highlighting what they tell us about a narrator's identity and perspective as well as how different types of narrative may function as data. Next, we introduce a basic method for analyzing narratives as networks, showing how structure can illuminate meaning. The section that follows traces significant developments in the approach over the past decades, including advancements in how to compare narratives and analyze different forms of discourse. Finally, we discuss several contributions and limitations of the approach.

What Is a Narrative?

Narratives are a particular kind of data, profoundly distinct from the abstracted variables that dominate most quantitative approaches to social science. Narratives offer an "account of a sequence of events in the order in which they occurred to make a point" (Polletta et al., 2011: p. 111). Like stories, narratives have characters (or, as Pentland and Feldman, 2007 call them, *actants*), who can both act and be acted upon (Gerteis, 2002; Polletta et al., 2011). But beyond characters, narratives weave events together into a plot; the choice of which events out of many to include – and how they are connected – reveals much about what point the author is trying to make.

Everyday, our lives are filled with a multitude of events: we wake up, we get up, we brush our teeth, perhaps we make and drink coffee, and some days we take a train to work. Most of these events are background to the story of our lives, though once we know what is important or significant or worthy of attention, some elements may rise to the foreground of a particular narrative. If one were living in Madrid on 11 May 2004, the fact that one took the train to work could turn out to be a very significant event in the story of a city terrorized by a bombing. In constructing a narrative, an author decides not only what to include, but also makes claims about how the elements of the narrative are related to one another. These claims could be causal (e.g., "because I took a later train, I arrived at the station after the bombing") or temporal ("after I

arrived at the station, I observed the carnage"). Taken together, causal and temporal connections create the plot – or theory – of the narrative. An account without causal or temporal links between elements is simply a report, with no narrative beginning, middle, or end (Bearman and Stovel, 2000; cf Polletta et al., 2011).

Types of Narratives

One important type of narrative is the *life story*. Told at a particular moment in time, a life story is first-person account of a life. Some life stories, those that take the form "I was born, I went to school, I married, I enjoy bicycling…" have little narrative, in the sense that they have no plot, and therefore no point. In contrast, a *narrative life story* is an account of how a person came to be the person she believes she is. In narrative life stories, the selection of events in the life, and the temporal and causal claims about how they are related to one another, provide insight into the author's theory of self. While narrative life stories are revelatory of the theory of self, an author's ability to tell her own life story may be constrained by her ability to express herself, her educational background, or the cultural or historical goods she has to work with.

Some narratives, including some narrative life stories, orient toward a particular *script* (Polletta et al., 2011; Gerteis, 2002). Scripts can be produced and reinforced by institutional structures as well as cultural expectations (Polletta et al., 2011: p. 112). When institutions are strong, they channel actors through particular social settings and provide an interpretation of events that can be reflected in a narrative. Similarly, culture, in the sense of shared symbolic meanings, offers cues about how things work and what they mean. Both institutions and culture therefore may suggest the plot of a narrative, regardless of the particular elements the author has to choose from. For instance, in contemporary Western societies, a culturally expected account of how one came to be married might involve details of how two people 'happened' to find each other, and immediately – or slowly – recognized their shared and deep attraction. This expected script differs dramatically from the accounts one would find in societies dominated by institutions of arranged marriages, where the actions, preferences, and interests of the couple would play a minimal role in the narrative. Religious and therapeutic organizations often encourage their members to adopt a particular narrative form to describe their journey toward transformation, e.g., "I was lost, and then I was found." By embracing an accepted narrative structure – and with it the associated theory of how things come to be – an actor can signal to others that she views herself as a member of a particular community (Polletta et al., 2011: p. 118). Yet while conforming to an institutionally or culturally supported script can convey belonging, deviating from expectations about how something came about can also produce powerful narratives. In a collectivist society like Japan, telling a life story that attributes success to hard work and personal accomplishment might shock and confuse (or inspire!) listeners.

Whether a narrative recounts a life history or some other event, it is often possible to find stories told from *multiple perspectives*. The existence of multiple accounts of the same or related phenomena is one of the factors that make narratives of interest to social scientists. While individuals might always be interested in the current version of their life story, it is the possibility of integrating or comparing multiple accounts of an event or process – either told by different people, or at different points in time – that allows us to move beyond the realm of journalism and yield insight into general features of social and political life. Analysis of multiple related narratives may reveal the existence of a normative script (Quinlan and Quinlan, 2010; Gerteis, 2002), may help define the boundaries of an event (Bearman et al., 1999), or may shed light on the process by which individuals come to share a sense of belonging to a common community (Smith, 2007; Lee et al., 2010).

Narrative Networks

The narrative network approach was developed by Peter Bearman and introduced in a short series of papers (Bearman et al., 1999; Bearman and Stovel, 2000). Narrative networks represent a method for distilling the *structure* of a narrative in order to recover its meaning. The approach rests on recognition of a fundamental similarity between narratives and networks, in the sense that both are characterized by distinctive patterns of connection between elements or events. A narrative is distinctive not just because of the particular set of elements it includes, but because of the particular connections the teller imposes on those elements. Similarly, a network is defined not just by who is in it, but also by the pattern of connections that link (or fail to link) the various actors. As Smith puts it, "It is a narrative's structure that allows us to analyze functions and patterns among constitutive units both within and across narratives" (Smith, 2007: p. 23). The idea that one can represent narrative text as a network or graph opens up a whole range of analytic tools that allow us to systematically summarize and compare extended narratives (Mckether et al., 2009).

To construct a narrative network, the scholar identifies each discrete element of the narrative and codes these elements as *nodes* in a network. The discrete elements can reflect persons, places, and things, author's realizations, or other details included in the narrative (Bearman and Stovel, 2000; Lee et al., 2010: p. 3). In most applications of narrative networks, nodes are coded inductively, though Shostak and Fox (2012) consider the advantages of coding for themes identified a priori. Pairs of nodes are connected by a directed link (an *arc)* whenever the author of the narrative imposed a narrative clause between the elements – where a narrative clause is a statement "that is temporally ordered in such a way that moving it involves changing the meaning of the sub-sequence in which it is embedded" (Bearman et al., 1999: p. 512). Thus arcs connect elements in the story only when the author imputes a causal or cognitive connection between them; purely temporal orderings are typically not coded links between nodes.

Bearman and Stovel (2000) offer examples of the process they used to code the life histories of Germans who joined the Nazi party before 1930. For instance, they provide the following segment of narrative text:

> When I was sixteen years old my mother bought me some brown trousers. If she had known the significance of this color, she would

never have bought them for me. I told her that they pleased me, and she also bought some for my brother… Now I felt as though I were half a Nazi." (Bearman and Stovel, 2000: p. 76).

They then transform this text into a set of unique elements, including:

- Mother bought brown trousers.
- Trousers pleased me.
- Told mother the trousers pleased me.
- Mother bought trousers for brother.
- …
- Felt like 'half a Nazi.'

Once the entire story is so coded, the narrative is transformed into an adjacency matrix, where the rows and columns represent elements in the story and cell entries represent narrative connections between nodes. After a narrative has been represented as an adjacency matrix, it is relatively trivial to analyze the narrative formally as a network. Various network measures, including reach, density, component size, and centrality can provide a summary of the structural properties of the network (Wasserman and Faust, 1994).

Following the practice of network analysis, an adjacency matrix can also be visualized as a graph; this graphical representation – which we can think of as a map of the narrative – reflects the structural connections between elements of the narrative. An illustrative graphical representation of a narrative account of becoming a Nazi is shown in **Figure 1**.

In Bearman and Stovel's study of accounts of becoming a Nazi, the primary analysis focuses on comparing the local density, centrality, and narrative reach of elements in the first and second half of the narrative. Narrative plot, they argue, is "locally dense, often cyclic, knotted, and characterized by a redundancy of ties" (Bearman and Stovel, 2000: p. 71). Thus they believe that an author's account of how something came to be (in this case, how a person became a member of the NSDAP) will involve dense subsequences of mutually reinforcing events – a structure of connectivity that is easy to detect by measuring local network density or node-specific reach. "By focusing on [betweenness] centrality, narrative process at the level of the element context is revealed. This process can, and does, differ from the explicit theory proposed by the author, for element centrality may be invisible in the unfolding narrative, as the most important nodes are those that bridge subsequences. … The structure of a narrative network provides insight into a motive, without exogenous imputation" (Bearman and Stovel, 2000: p. 88).

Figure 1 Graphical Representation of a Narrative Network (Figure 2 in Bearman and Stovel 2000).

While the process of identifying nodes and determining the presence of arcs may appear straightforward, many complexities arise, particularly when the aim is to integrate multiple narrative voices, or to compare across narratives. This issue is addressed in different ways in different studies; one aspect of Bearman and Stovel's approach is to classify nodes into categories, and examine the pattern of ties within and between categories (see also Gerteis (2002) for a similar approach). They begin by differentiating nodes based on the function of the element in the narrative. In their study of the life histories of early Nazis, they classify each node as either a macrolevel event (*M*), a local event (*L*), or a cognition (*C*).

Macro-level elements are elements noted in the narrative that occur outside the author's local world. In this narrative, macro-level elements include the 'great war', the putsch, and rising inflation. Local event elements are ordinary events occurring in the author's local world. These are events that are experienced directly. In our illustrative story local elements include experiencing a childhood illness, wearing a swastika to school, and taking a bicycle trip with his sister. Cognitions are aspects of the narrative in which the author questions the meanings of elements, draws conclusions, or reveals a new cognitive understanding about his situation. Cognition elements include 'communists and Hitler both want power', 'recognizes the beauty of nature', and 'felt as if half a Nazi.' (Bearman and Stovel, 2000: p. 83)

Analysis of the distribution and pattern of connection between *M*, *L*, and *C* elements reveals the important role cognitions play in connecting and animating local events during the process of becoming a Nazi. Beyond the function of events in the narrative, Bearman and Stovel also classify events in terms of their content – a strategy that others adopt in later work. In the case of the life stories of early Nazis, events are coded into a series of concepts or themes (see also Mckether et al., 2009) that reflect factors others have identified as important for high-risk mobilization processes. These categories include chaos, exposure to other Nazis, anti-Semitism, order, and the elision of social relations.

Bearman and Stovel's analysis of life histories as networks reveals a profound difference between the structure of the narrative that described the process of *becoming* a Nazi and the portion that described the author's life as a Nazi (the *being* story). While the *becoming* narrative is composed of complex,

dense, and connected subsequences of elements involving cognition, the *being* story is sparse and relatively unconnected. Things just happen, but there is no narrative glue stitching them together. Bearman and Stovel argue that this sparse narrative structure is characteristic of the adoption of a total identity: it is as if for such actors, history stops, and they live their life with the zeal of one who embraces an ideology that answers all questions for them. "Nothing is left to operate the story, except for a mechanical agency…. The authors of the stories we consider can continue to report the facts, but nothing beyond the facts. This is not because there is not a story to tell: they explicitly select facts to tell a story, but it is a banal story of action without actors" (Bearman and Stovel, 2000: p. 89).

Extensions of the Method

Integrating Multiple Narratives

In another early example of narrative networks, Bearman et al. (1999) analyze the relational structure of multiple narratives. Rather than focusing on the processes of identity formation, Bearman and his coauthors use the life stories of Chinese villagers from one small village to better specify the bounds of a historical incident, thereby aiding in the interpretation of the events within the case. This study, despite its dissimilar aim, complements Bearman and Stovel by highlighting how narrative networks help reveal the meaning hidden in personal histories.

Bearman et al. (1999) use narrative networks to address a significant obstacle in historical analysis: the problem of the future. As the authors put it, "only when we can provide the beginning and an end to a sequence of interrelated events can we understand the meaning of an event within the sequence and, by extension, the meaning of the event as a whole" (Bearman et al., 1999: p. 502). Yet, how are we to know when a historical incident ends? In considering this question, these scholars exploit the parallels between narratives and networks, arguing that demarcating the beginning and end of a historical incident, or 'casing' the incident, is similar to specifying the boundary of a network. The boundaries then tell us about the historical incident's fluidity, or its ability to be conditioned or activated by future events. The theoretical argument is that the more redundant or interdependent the relationships between the constitutive events within the boundaries, the less likely it is that the meanings attributed to those events will change.

Bearman et al.'s analysis is innovative in that it integrates multiple narratives describing the 'same' historical event into a master narrative. Using a strategy similar to that described in Bearman and Stovel (2000), they first code the historical events contained within 14 different life stories as nodes. They then assign ties between nodes connected by narrative clauses or clauses that temporally connect events within a narrative. Yet because their data include different narrators describing the same events, the structure of paths between nodes varies, depending on how each narrator understood the historical events. At this stage, Bearman et al.'s approach diverges from the Bearman and Stovel method: rather than analyzing each narrative separately, Bearman et al. build an integrated network via the nodes shared across narrative. In this new narrative network, nodes are connected if there is a tie between them in any of the original networks. Thus the final narrative network captures how the 14 narratives articulate with one another.

The key step in the analysis of casing is identifying a 'bicomponent' in the interrelated network. This is a component, or maximal connected subgraph, where "all nodes are connected by at least two independent paths and where the addition of a node requires that it is connected to two nodes in the subgraph" (Bearman et al., 1999: p. 517). A bicomponent, the authors argue, provides a candidate for a 'cased' historical sequence. If a researcher simulates new networks based on the integrated narrative, and finds that the bicomponent is highly resilient to perturbations, it is reasonable to conclude that the meaning of the events constituting the bicomponent are historically stable, in the sense that the meaning is unlikely to be changed by future events. Researchers are more likely to agree on the bounds of the case and, therefore, more likely to agree on the meaning of events within the case. In contrast, finding fragile networks reduces our confidence in the meanings ascribed to the events. This, in itself, is an important insight to how we interpret networks. While many analysts specify the boundaries of networks by finding partitions between clusters, Bearman et al. note that these connecting arcs may in fact represent important links in a historical case.

Aggregation and Comparison

In a fascinating comparative study of ethnic identities among ethnically Italian and Croatian Istrians, Smith (2007) further develops narrative network analysis by introducing a new strategy for comparing multiple, and sometimes contradictory, narratives. Smith draws on over 200 narratives collected from Istrians living in Italy, Croatia, and New York City to explore "the ambiguous space between two hardened social identities" (Smith, 2007: p. 23). Her analysis shows how narratives of ethnic violence have helped maintain sharp social boundaries between Italian and Croatian Istrians living in Europe, while the narratives of Italian and Croatian Istrians who moved to New York City have blurred ethnic boundaries and reveal the emergence of a shared Istrian ethnic identity. The goal is "to produce an understanding of how meaning emerges from the structure of relations among narrative elements, just as social meaning emerges from the structure of social ties" (Smith, 2007: p. 24).

Smith's key methodological contribution is a method that allows her to identify abstract elements (themes) that are likely to play a role in multiple narratives. Following Gerteis (2002), Smith seeks to identify shared, or collective, narratives, which "emerge when regularly occurring plots connect to key characters in an empirically stable way" (Gerteis, 2002: p. 593). Smith first recognizes that events can be nested within other events and, when grouped and sequenced, these groups of events – which often include a combination of local and cognitive events – form aggregated *narrative elements* (e.g., notions of liberation, victimhood, relocation). She explains, "Aggregate elements are defined by sequences of events that contribute to the element's meaning; an understanding of how aggregate elements are tied together requires an understanding of the array of relations among the events that compose the aggregate element" (Smith, 2007: p. 26). In other words, the meanings of the aggregate elements that provide the

foundations for the narrative's plot depend on how specific events are interpreted by the narrator. And, since different narrators may interpret events differently, the aggregate elements are likely to mean different things across narratives – especially when narrators fall on opposing sides of ethnic conflict. Following Bearman et al. (1999), Smith claims that the robustness of the structure of ties between events reveals when elements are vulnerable to new interpretations. Thus, "the reorganization of relations within discrete aggregate elements is likely to be the locomotive for change in the narrative as a whole" (Smith, 2007: p. 27). Smith's aggregation technique allows her "to identify which relations among the lower-level events have changed in order to produce changes in meaning at the level of abstract element and, subsequently, of the narrative as a whole" (Smith, 2007: p. 42). This approach shows how the meanings of aggregate elements in narratives of ethnic violence demarcate the social boundaries between Italian Istrians and Croation Istrians living in Europe.

At the same time, some aggregate elements are likely to be *shared* by narratives from each side of the social boundary. Smith terms these aggregate elements 'boundary elements' and, while they may differ in meaning, they link narratives together. This can have notable consequences when narrators begin to interpret the boundary elements' constitutive events differently, thereby changing their meaning. When this occurs, boundary elements can fuse together distinct narratives. Smith shows, for example, that when Italian and Croatian Istrians in New York began reinterpreting the events surrounding Istrian victimization and the role of Italian Istrians who remained in Istria (instead of fleeing to Italy), they were able to merge 'the opposing narratives and smooth over differences' (Smith, 2007: p. 39).

This conceptualization of boundaries and the comparative approach more generally leads Smith to propose a different perspective on the relationship between narratives, causality, and identities. Whereas Bearman and Stovel (2000) used the narratives of Nazis to gain insight into the processes of identity formation (i.e., *becoming* and *being* a Nazi), Smith focuses our attention on how differences in narratives can cause a change in the nature of an identity over time. When Italian and Croatian Istrians socialized in New York City, they had reason to reinterpret the events of the original narratives. This resulted in transformed narrative elements, including boundary elements, which then led to a new unified Istrian narrative and a panethnic Istrian identity.

Institutional and Individual Narratives

In another innovative study, Quinlan and Quinlan (2010) advance the use of narrative networks by examining the types of narrative structures that may exist in nonstory forms of discourse (Polletta et al., 2011). In their comparison of a rape narrative told by a victim – what they call the 'lived experience' – with an institutionalized representation of rapes produced through official reports, Quinlan and Quinlan seek to identify the 'line of fault' between different forms of discourse. Their finding reinforces our intuitive understandings of narrative: the victim's story is driven by the recounting of the event, while the institutionalized report is a disjointed account centered on cataloging the identity of the subject, with little plot to glue the account together.

Quinlan and Quinlan begin by collecting the institutional texts – in this instance, forms from sexual assault evidence kits that record data from a series of questions posed to the victim concerning the assault. Roughly following Bearman and Stovel's substantive classification of nodes, they categorize their information into thematic elements (see also Shostak and Fox (2012) for thematic coding). For example, name and address are grouped under the larger thematic element of 'her identity.' These elements serve as the nodes of the network; connecting arcs represent links between elements. As a comparison case, they analyze a published narrative account of a rape and identify themes based on a selection of sentences or phrases that they deem most representative. These themes become nodes, which are then linked based on the thematic flow of the story.

In their analysis of the story of the rape, Quinlan and Quinlan's narrative network reveals the node 'his action' (i.e., the act of rape) is the driver mode, in the sense that it is the node from which all other nodes in the network of the narrative follow. Calculating the centrality score associated with each node, however, reveals that 'terror' is the most centralized node, while, local, lived experiences outside the rape exert no influence on the narrative. In contrast, the institutionalized representation of the rape has no driver node; the institutional text is comprised instead of clusters of thematic elements isolated from one another. With no narrative path through the institutionalized networks, the authors turn to a measure of centrality, and find that the identity of the victim – 'her identity' – is the most central thematic element in the text (even more centralized that the 'assault' node). It is interesting to note that Quinlan and Quinlan find that 'her identity' is the primary theme in the unconnected institutional texts whereas Bearman and Stovel's analysis reveals that the self disappears in the unconnected *being* narrative (Bearman and Stovel, 2000: p. 89).

Quinlan and Quinlan's study presents an approach to comparing narrative networks that emphasizes differences in the narratives (and meanings) that emerge from the stories of 'real,' lived experiences and the abstracted institutionalized renderings of those experiences. The comparison presents us with two models of identity. One is the personal identity, which is constructed via the connection between specific and detailed recollections of an experience; the second is the institutional view of identity, which is constructed using details abstracted from the actual experiences of the person. While the authored narrative has actors and agency, the institutional identity is all about figuring out who is who. This is the 'line of fault' between these two types of text. By contrasting these two types of narratives, Quinlan and Quinlan advance the 'narrative turn's' awareness of institutional context (Polletta et al., 2011), demonstrating the usefulness of narrative networks in revealing the forces by which institutions coordinate our identities and experiences.

Contributions and New Directions

The narrative network approach offers both a methodological tool and a framework for theoretical insights. Methodologically, it is one of a very small number of techniques designed to facilitate what Mario Small refers to as 'crossover analyses'; analyzing qualitative data with formal, quantitative methods

(or vice versa) (Small, 2011). Indeed, the narrative network approach rests on gathering large amounts of qualitative data and conducting systematic comparisons and analysis of network structure derived from the texts. As such, it can be applied to a wide range of substantive problems – as long as they were captured by stories.

At the same time, this approach is theoretically generative. Instead of producing causal models of what factors caused a particular outcome to occur, the narrative networks approach instead offers insight into how actors – or sets of actors – interpret and understand historical events and social phenomena. Especially when it is used in a comparative design, narrative networks' strength is that it makes it possible to identify the structure of common scripts, collective narratives, or changes in narratives, thereby 'fleshing out' a historical period or past experience.

However, as with other social scientific approaches that provide scholars with both methodological tools and theoretical insights, the use of network narratives raises several challenging issues. In this final section, we highlight some key obstacles associated with the narrative network approach. We view these limitations less as conceptual flaws and more as opportunities for further advancement and development.

Methodological Challenges

Sources of Data

For many research problems, the relevant narrative data are more complex than single-authored life stories of the type that dominate the studies described here. As in Quinlan and Quinlan (2010), textual data may come from official records, but they could also reflect second-hand accounts, transcripts of group interviews (Mckether et al., 2009), or organizational representations of events (Gerteis, 2002). Appropriate analyses of such diverse types of narrative will require further developments of narrative network techniques, and perhaps better appreciation of the consequences of selection bias in the sample of narratives. And yet since some types of qualitative data are not 'narratives,' – in the sense that they do not have a plot – the payoff of employing the narrative network for some types of data approach may be unclear. Thus this methodological issue surrounding different types of narrative data raises theoretical questions about what network structure can reveal about collective understandings, and the coercive power of strong narrative scripts.

Coding of Data

The majority of research using the narrative network approach employs a simple formula of coding nodes as events (Bearman et al., 1999; Bearman and Stovel, 2000; Quinlan and Quinlan, 2010), themes, or a combination (Smith, 2007) and arcs as the narratives clauses, causal relationships, or connecting relationships. Yet with each new study, new issues associated with coding emerge. When is a narrative element significant enough to warrant becoming a node? What constitutes a link between nodes? A key assumption of the approach is that arcs represent causality from a narrator's point of view, a perspective that may very well be at odds with other – perhaps more accepted – points of view. To draw from an example given by Lee et al. (2010), when dealing with the statement 'increased political tension in the middle-East drove the gas price up' the traditional narrative network approach would create a path between 'increased political tension in the middle-East' and 'gas price going up,' because the narrator believed it to be true. However, if historical evidence contradicts this, how do we understand the meaning of this arc?

Time

Applying the narrative network method raises many complex issues about time, timing, and temporality. Beyond the question of how to represent temporal flow in the coding of text, working with narrative data may reveal that an actor's narrative account itself changes over time, as her understanding of the situation changes, or as the institutional or cultural context shifts (e.g., Shostak and Fox, 2012). While a narrative network represents the temporal sequencing of events from one vantage point in time, many important questions revolve around how narratives change over time. Bearman et al. (1999) argue that when multiple narrative networks produce a stable bicomponent, the narrative meaning of a historical event is fixed. Does an analogous process operate when an individual tells his life story at multiple moments in time?

Theoretical/Interpretive Challenges

The second major challenge facing scholars using narrative networks concerns how to make sense of the findings. This, of course, is related to how narratives are coded and what network analyses are conducted, but at a more conceptual level, we must consider what narratives can and cannot tell us about the author's world.

We begin by focusing on the author of the narrative – the original subject of narrative networks – and ask what insights narratives give us into the multilayered, hierarchical identities that people have. Bearman and Stovel (2000) fix their gaze on the development of a 'master identity,' a concept that is clearly relevant for those, like Nazis, with strong ideological orientation. But most persons do not claim a master identity; in fact, social life is particularly interesting and fraught with ambiguity when actors must determine what identity to deploy in a particular situation. The tools of narrative networks have not been applied to research problems that focus explicitly on the choice of what identity people use in different settings, and yet it seems reasonable to hope that narrative networks will enable us to gain insight into the layers of identities and meaning that reside in an author's interpretation of their experiences.

Another theoretical question concerns how to connect a narrative to the cultural and institutional context that it is embedded in. Exactly because institutions and cultural context provide the background for narrative, crucial aspects – even, from the narrator's perspective, *causally* crucial aspects – may be omitted from the told tale. These omissions may lead an analyst to fundamentally misunderstand the author's intended plot. One way forward is to follow Bearman et al. (1999) and Smith (2007), and analyze multiple narratives of the same events, with the hope that the integrated narrative will point toward important cultural frameworks guiding the narrative accounts, yet neither of these studies explicitly theorized how context shapes narrative understanding.

Even more challenging is to understand how the telling of narratives – whether by individuals or through the

development of collective narratives – impacts institutions, politics, culture, or social organization. Much research lumped under the broad narrative umbrella claims narrative as a resource that can shape the social environment, and yet to date, the narrative network approach has not been used to explore how narratives can be deployed to effect change. Important questions include Does the extent to which a narrative account is shared matter? Does it matter how a narrative dovetails with empirically verifiable facts? These issues become even more intriguing given the emergence and spread of real-time communication technologies (e.g., social media, cheap and accessible mobile devices), which result in the proliferation of nonnarrative forms of discourse. For instance, future scholars might use narrative networks' approaches to compare revolutionary narratives produced in Egypt (2011) to those written about Nasser's 1952 Egyptian revolution. This and other challenges make us optimistic that the narrative network approach can grow beyond its founding link with historical sociology and more fully engage scholars and disciplines focusing on social change.

Abstract

Narratives are ways of linking together past events, making sense of historical or fictional personae. There exists a multitude of genres that draw on diverse academic traditions, ranging from legal studies and sociology to literature and hermeneutics.

This article explores discursive approaches to narratives, studied as situated *social action*, focusing on storytelling, rather than on the stories as such. In courtroom examinations, medical interviews, everyday blame allocations, and other contexts where stories matter, narrative action involves numerous storytelling devices: e.g., social accounts, reported speech, and social categorizations. The conversational work of narrators also invokes participation frameworks and audience design.

The Narrative Turn and Technologies of Selves

During the last two decades of the past century, social theory has undergone a narrative turn. Before that, Wittgenstein's (1953) work on language games had broken new ground in legitimizing the study of language usage, moving beyond a study of language as a fixed set of structures. Contemporary analyses of narratives feature work – not only on language games, ambiguity, and fuzzy concepts – but also on storytelling procedures, alternative versions, and contested stories. Some of these new directions, including the idea of intertextuality, genre, and audience design can be traced to Bakhtin (1981) and the importation of concepts from literary theory into the social sciences. Simultaneously, a novel focus on sequential unfolding, and micro-politics draws on Goffman (1961, 1967, 1981), Sacks (1992), and new developments within sociology, anthropology, and linguistics. In order to understand a story fully, it is necessary to know something about where, when, why, to whom, and by whom the story was told. In work on narration, analyses of subversion are closely related to dramaturgical aspects of storytelling: as in a focus on participation frameworks, that is, on speaker/listener roles (Goffman, 1981).

In his historical societal analyses, Foucault has discussed how dominant stories have been employed in the colonization of selves. Foucault's discussion of the technologies of selves (1997), presupposes that our public selves are intimately linked to conversational practices. His analysis of the historical roots of self-technologies links such technologies loosely to self-reflexivity practices and to early forms of self-confessions. In the case of early Greco-Roman philosophy, or in monastic confessions in early Christian spirituality, the self was narrated in more or less monological formats, e.g., in letters to friends.

Interviewing, teaching, counseling, and therapy can be seen as prototypical discursive technologies for eliciting what Foucault calls confessions and authoritative responses to such confessions, e.g., judgment, evaluation, celebration, and discipline (Foucault, 1997). In modern society, confessions have become integrated into what Foucault calls *truth regimes* that organize institutional practices in normative patterns for what should be told to whom and in what ways. In modern life, there are several discursive genres that can be related to the formation – and reflection – of moral order and selves in a Foucauldian universe. Such genres are important in discursive practices, but Foucault himself does not detail how such identity work is done on a conversational level.

In folkloristic and ethnographically oriented sociology, life-story interviews have been key methods in the formulation of reflexive analyses of everyday action. Traditionally, interviews have been the main tools for eliciting life stories or story fragments. However, what has been analyzed is normally the life story as such, not the storytelling. But, since the 1990s, ethnographic and anthropological work on life narratives has turned toward procedural aspects; that is, to the storytelling, as well as to how narratives are linked to the formation of selves in different cultures (for reviews, see Gubrium and Holstein, 2008; Ochs and Capps, 1996). In line with the work of Bamberg (2011) the focus is often on small stories rather than on grand narratives. Analyses of such storytelling practices are particularly illuminating, as they combine life-story material with natural data not primarily elicited for the benefit of the interviewer. In a Foucauldian universe, education is seen as one of the technologies of the self. It is not merely an issue for formal schooling, but also for informal schooling in family-life contexts. In work on family dinner conversations, it can be seen that narratives are deeply embedded in family politics that are, in turn, shaped by cultural norms for participation. In their analyses of agoraphobia in ordinary family conversations, Capps and Ochs (1995), for instance, illuminate the ways in which panic is displayed and co-construed within the everyday narratives of a family where one member suffers from agoraphobia. Through her mundane panic stories, the mother reveals her fears, but she also passes on patterns for how to construe the world as a fearful place. In their detailed analyses of this troubled family's dinner conversations, Capps and Ochs (1995) identified narrative patterns, reflecting underlying family hierarchies.

One of the main methodological controversies in recent work on narration concerns the relative role of text and context. The work of Foucault, as well as much ethnographic and traditional sociological work, is primarily focused on contextual aspects of discourse. In contrast, conversation analysis is primarily oriented to the text as such and to intersubjectivity (the dialogic production of narratives). Context is in focus only in those cases where it is actually invoked by the participants

themselves (Schegloff, 1997). In conversation analysis and ethnomethodology (Heritage, 1984), phenomena such as dominant narratives are thus primarily seen as participants' phenomena (see also, Sacks, 1992). It is only if domination is invoked by the participants themselves that it is actually taken up in the researcher's analyses.

Contemporary narrative models (Bruner, 2004) position language and the role of narration in the foreground in the formation of minds. Similarly, narratives are seen as the basic building blocks for imagined communities (Andersen, 1991), in that the very notion of community is often based on historically grounded, or oppositional narratives. In fact, the social sciences are based on local ways of building narratives and on the type of language varieties involved (Rorty, 1980).

Social Action and Technologies for Building Stories

Some contemporary models are deliberately 'mindless' in that they are more oriented toward procedural aspects of narration: how narratives evolve sequentially and how they are co-construed or deconstrued as part of social action (Drew, 1992; Galatolo and Drew, 2006; Goodwin, 2007; Sacks, 1992; Schegloff, 1997). Sacks (1992) investigated the interactional features of a variety of narrative practices, such as telephone calls to a suicide center, problem formulations in therapy, and the telling of jokes. His lectures on conversation primarily discussed the turn-taking machinery, the dialogical and sequential organization of conversational turn-taking (Sacks, 1992). Yet they also cover entitlement to stories, tellability, and what he called 'a technology for building stories.'

More recently, there have been discussions concerning how talk in action, that is, dialogic mechanisms for storytelling and speaking can be seen in courtrooms and other institutional settings (Drew, 1992; Heritage and Clayman, 2010; Lynch and Bogen, 1996). Such interactional analyses of narratives focus on the *storytelling* or the narrating, not on the static structural aspects of traditional narrative analyses of stories. In the realm of interactional theories, the micro-politics of identity work in institutional settings has been documented in a series of analyses of contemporary institutional narratives. There are many genres of such narratives: for instance, couple therapy (Buttny, 1993), and suspects' and defendants' storytelling in police interrogations and courtroom examinations (Drew, 1992; Galatolo and Drew, 2006; Lynch and Bogen, 1996; Stokoe, 2010), as well as in anamnestic contexts (e.g., Heritage and Robinson, 2006). All these genres have implications for identity formation, both for displaying identities and for cocreating identities. This Janus-face nature of conversations and selves is also an essential feature of ethnographic and conversational work on narratives and self-identities.

Narrative Devices

Much research on narratives has centered on the structure of plots in relation to various elements (such as background, future events, introduction of main characters). The temporal order of the narrative has long been a key element of narrative organization as in Labov's (1972) classical analyses of oral narratives of inner-city youth. Minimally, a narrative scheme involves two temporally ordered events. In the more elaborate type of fight stories and other personal narratives that Labov elicited from inner-city boys, it is often possible to discern a more complex pattern involving abstract, orientation, complicating action, evaluation (what is the point?), resolution, and coda (is there a signal that the story is over?). Yet, the sequential order of storytelling need not coincide with the temporal organization of the tale. In a critical discussion of narratives and cognition, Edwards (1997) demonstrates ways in which script models and other structural models (for example, Labovian schemes) in fact do not hold up in the face of the complexities of mundane interaction; they collapse when they are applied to real-life online narration in interactional contexts.

Interactional analyses of storytelling events are therefore important tools for sharpening our reasoning on narration as '*social action*.' Such work focuses on participants' orientations to coparticipants and to the narrated events, rather than primarily or only on the temporal framework of the story. The narrator's affective stance or point of view can often be detected in linguistic cues such as pronoun choice or passive versus active verb forms (Goodwin, 2006, 2007; Ochs and Capps, 1996). In some cases, linguistic resources can be seen to index stances that are closely related to conversational or institutional genres (Bakhtin, 1984; Lynch and Bogen, 1996), such as assessments or complaints. In interactional work on narration, genre is therefore not merely seen as a background variable for talk, but rather as an outcome of the interaction as such. In many institutional encounters, it is, for instance, the powerful party who engages in authoritative moves, such as reformulating what the story is about (Sacks, 1992). Conversely, this means that speakers may position themselves as people in power through exploiting discursive devices that are associated with institutional authority.

The intersubjective architecture of confessions was discussed in Sacks' (1992) lectures on conversation. In telling 'a first story,' a speaker may invite 'a second story,' and categorizations and first assessments often precede second assessments. In everyday conversations between friends, disclosures of secrets or taboo or delicate information may similarly invite disclosures by copresent parties. Disclosures similarly tend to assume a sequential structure, involving fragmented and gradual revelations. Similarly, Goodwin (2006) has demonstrated the complex sequential structure of preadolescent girls' adversative storytelling by showing how they would animate and enact characters, using reported speech in casting someone as blameworthy, while simultaneously securing the alignment of other copresent parties. Moreover, the girls would draw on social categorizations, such as 'tag along' in creating social exclusion. Blame narratives were therefore resources for co-creating inclusion/exclusion and peer group order.

The written record is obviously an important resource in the technologies of selves. Cicourel (1968) revealed ways in which written police records were ultimately the products of talk; that is, the products of extended oral negotiations. Recently, Lynch and Bogen (1996, p. 203) specified many ways in which courtroom dialogue may be 'on the verge of breaking into

writing,' as in the Iran–Contra hearings in which prepared written statements, documentary exhibits, citations of prior testimonies, and written notes played a prominent role in the defendant's 'spontaneous' oral response to questions in the public hearing.

Written narratives tend to look more objective or factual than oral narratives. Yet, many written documents obviously emanate from talk-in-interaction. The delicate interplay between written and spoken language can also be seen in other institutional settings than courtrooms. In his work on answering patterns at a suicide prevention center, Sacks (1992), for instance, showed that the professional's answering sheet influenced the order in which she/he asked questions, illustrating how the design of written forms and records is important for the formation of oral narratives.

In several institutional practices – e.g., medical consultations, trials, and psychotherapy – an important part of conversational action is to identify the problem. Competing problem formulations are therefore key elements in such institutional narrations (e.g., Aronsson and Cederborg, 1994; Aronsson and Osvaldsson, 2014; Lynch and Bogen, 1996; Stivers, 2007). Narrations that are related to self-presentations entail substantial moral work in that they project different positions within a given social order. But in conversational studies of narration, control is not restricted to fixed positions in local hierarchies. Within the medical arena, it has been shown that doctors influence patients' problem presentations in a series of ways, for instance, in how they design their opening questions (Heritage and Robinson, 2006); whether they invite anamnestic narratives through a general inquiry (e.g., 'so tell me about this pain you are getting') or whether they merely ask for anamnestic confirmations. However, patients also influence doctors, and prescriptions of antibiotics can partly be seen as the outcome of social interaction, rather than medical concerns alone (Stivers, 2007).

Social Accounts and Character Contests

In institutional contexts such as therapy talk or interrogations, participants regularly present social accounts (Buttny, 1993; Stokoe, 2010) where they justify or excuse themselves in the light of implicit or explicit blame.

Narratives can be said to be located within epistemic territories (Heritage and Raymond, 2005) where participants recurrently assess story contributions with regard to credibility, entitlement, or other issues related to the local interaction order. Social action is, for instance, accomplished through upgradings and downgradings of narrative assessments, at times combined with tags (inviting coparticipants' agreement). Occasionally, such narratives actually form part of what Goffman (1967, pp. 239–270) has called *character contests* where not only past actions form part of assessments, but also the ways in which a target participant manages to account for mistakes or failure in convincing or compelling ways. In so doing, participants may invoke social categories to accomplish complaints, blame, accounts, or other types of social action (Stokoe, 2010). For instance, Sjöblom and Aronsson (2012) have shown ways in which adolescent boys during computer gaming conversations recurrently categorize each other as 'noobs' ('newbie,' incompetent) when accounting for player death or other category-bound events (linked to incompetent gaming). Conversely, skillful gaming is related to various ways of avoiding failure. What is important is that a player manages to present *social accounts* for past gaming in such a way that he does not risk being categorized as a noob, that is, as someone at the bottom of the local rank order. In their retellings (and accounts) of crucial game events, players are then ultimately assessed, not only with regard to gaming skills, but also with regard to their ways of accounting for or failing to account for unfortunate game performance, that is, their narrative skills.

Resistance and Social Categorizations

Dominance and power are classical sociological themes, but in the work of narratives in interaction, collusion, and subversion are equally important phenomena. Subversive action has been at the heart of sociological work on narratives, not only in the work of Foucault on societal institutions such as prisons, but also in Goffmanian work on mundane everyday negotiations. In many ways, narratives can be seen as battlefields for self-ascriptions and self-projections even if some of the battles are indirect or hidden. In his classical work on asylums, Goffman (1961) discussed the type of categorization work done by total institutions in their diagnoses of patients, as well as the patients' resistance to stigmatization. Ambiguous narrative roles (who speaks on whose behalf?) are also at the core of Goffman's (1981) work on participation frameworks and in Bakhtin's (1981) work on the multivoicedness of narration, but neither of these scholars has in detail documented the sequential unfolding of resistance.

Recently, resistance has, for instance, been analyzed in detail in Stokoe's (2010) work on *category-bound denials* in police interrogation storytelling where defendants claim that they would never touch members of a specific social category, for instance children or the elderly (e.g., 'I am not going to hit a lady'). Negotiations about social categories can also be seen in teenage girls' divergent story versions about 'bullying events,' where the same party can be cast as a victim or a bully, depending on who is telling the story to whom (Karlsson and Evaldsson, 2011).

Narratives in interaction are often contested, as language use is never disinterested – narrators always direct their narratives to someone, and they wittingly or unwittingly speak on somebody's behalf (Bakhtin, 1984; Goffman, 1981), adopting various affective and epistemic stances. Within an epistemology of a multivoiced or polyphonic universe, encounters also involve potentials for secret alliances and collusions. Such collusion can be seen in various institutional contexts, such as in asymmetrical encounters when there are dominant or authoritative voices, on the one hand, and subordinate voices, on the other (see also Heritage and Raymond, 2005).

In detailed analyses of small claim court interactions, it has been shown that narrative genres at times have collusive qualities. For instance, relationship-oriented and informal narratives need not be more egalitarian and democratic than

more formal rule-oriented narratives (Conley and O'Barr, 2005). In fact, inexperienced persons are often more at a loss in informal contexts, in that they are required to construe legal narratives on their own, whereas formal settings offer more support from legal professionals.

Silent opposition can also be found in public events. In legal contexts, witnesses are expected to be compliant. Yet in police interrogations, for instance, compliant witnesses may, through their collaboration, produce the very evidence needed for an eventual accusation (Lynch and Bogen, 1996). Institutional confessions or disclosures, therefore, often involve substantial downgrading of agency through impersonal constructions, vague or evasive responses, and minimizations of the offensive act. In their in-depth analyses of the Iran–Contra hearings, Lynch and Bogen (1996), for instance, demonstrate how the defendant Oliver North cleverly exploited his response turns, changing the genre of the trial during its 6 days on television. Through his military politeness, minimal responses, and strategic repetitions, he displayed an attitude of apparent compliance and respectfulness to the great media audience – the popularity of which was also reflected in an audience response of flowers, supportive letters, and successive transformation of an alleged villain of war into a public hero.

Moreover, the two authors present fine-grained analyses of the conversational management of staged spontaneity and strategic 'forgetting' of crucial events. For instance, Oliver North acknowledged lying in the past, but claimed that he would now tell the truth: "the good, the bad, and the ugly" (Lynch and Bogen, 1996, p. 38). On a deeper level, however, the analyses of Lynch and Bogen (1996) show how a well-prepared witness like Oliver North skillfully avoided responding to the important questions, undermining the interrogator's narrative, thereby indirectly mocking his interrogators. The trial was thereby changed into public entertainment; what Foucault would have called a historical spectacle as opposed to a serious courtroom interrogation.

Storytelling as Storytelling Contests

Competing narratives can, for instance, be found in family-therapy conversations. Aronsson and Cederborg (1994) demonstrate that therapy often involves underlying storytelling contests in which one side ratifies its own story, whereas the other side's story is deauthorized in that the story point is challenged or undermined. The therapist plays a key role as an intermediary – an orchestrator of who talks to whom about what – and as arbitrator about when a narrative is ultimately finished. But the therapists' control in family therapy is more concerned with issuing storytelling rights than with sheer dominance over turn taking. It primarily concerns what is reportable or tellable, as well as story boundaries, that is, when a story is to be told and implicit norms for when it is finished.

A pioneer study of oppositional work in legal settings can be seen in Cicourel's (1968) monograph on juvenile delinquents and the conversational work of parents, probation officers, and experts such as psychiatrists. Cicourel did not detail the conversational work as such, but he discussed the defensive interactional work of parents, showing, for instance, how middle-class parents recruited outside assistance from therapists and teachers, working on recategorizing their sons as depressive rather than as delinquent, or as temporarily influenced by peers rather than as active and willful. The written police record categorizations of 'delinquent' actions were therefore partly the result of extended parent–expert negotiations. In his micro-sociological analyses of parental storytelling in the face of alternative legal versions, Cicourel (1968) simultaneously shows that detailed ethnographic data need not exclude a concern for macro-sociological issues such as class.

In adversarial courtroom proceedings, trials can be seen as storytelling contests, in which each attorney must ask questions in such a way that his/her client tells the most convincing story. Credibility is thus largely a matter of narrative design, performed by the witness or the defendant and masterminded by the attorney. Such storytelling contests underlie various actions in adversarial courtroom contexts. Witnesses are positioned as members of either side's team (the prosecution or defense side), which means that, for instance, rape victims tend to be treated as prosecution team members, and are at times exposed to discrediting and damaging questions by the attorneys of the defense. In an analysis of an American rape trial, Drew (1992) shows that such trials may involve substantial resistance and strategic defense on the victim's part. In his detailed analyses of an extended episode from a rape trial, Drew shows that the rape victim employed alternative descriptions as well as other discursive devices in her story (of being merely an acquaintance of the rapist) as opposed to that of the prosecution (of her being a lover or willing partner). Yet, the two competing stories were told as fragments, sequentially revealed in the attorney's questions and in the witness' defensive and oppositional responses.

In a discussion of the (in)famous Rodney King case, Goodwin (2007) presents detailed accounts of how a victim's bodily movements as *reaction* to police violence can instead be transformed into prosecution side stories about incipient *aggressive actions*. In a recent study of parents' courtroom talk in child custody trials, Ingrids and Aronsson (2014) document a series of such radical transformations of agency, transforming protagonists of opposing story versions from victims into culpable parties and vice versa. Moreover, the analyses (Ingrids and Aronsson, 2014) document the role of exact quotes (direct reported speech) in enacting prior events, building credibility through alternative stories, rendering opinions both more vivid and authentic or 'objective.' These quotes were embedded in repeats, exaggerations, and at times even reported dialogues that embellished the contesting narrative versions. Reported speech simultaneously provided a unique resource for including the absent child's positions in this courtroom context, an important rhetorical device for validating both authenticity and epistemic authority. The testimony reveals that the parent actually *heard* what happened, and it animates the absent party, putting the listener in the child's place through vivid descriptions.

Interaction Order and Identity Work

In everyday life, character is recurrently at stake, first in the ways that participants manage to act in line with the local interaction order and second, in the ways that they manage to explain

failure or success and to account for past action in such ways that their actions will not be contested. These narrative contestations therefore invoke two types of selves, the selves of the participants themselves, on the one hand, and their narrator selves, on the other.

Nation, Sociological Aspects of

André-Paul Frognier, University of Louvain, Louvain-La-Neuve, Belgium

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The concept of nation and the sociology of nation are discussed in their historical contexts. The distinction is drawn between those authors taking a 'modernist' viewpoint – that the nation is a truly modern invention which takes the form of an imaginary community – and the 'primordialists' concerned mainly with the historical roots of the nation. Globalization and cultural homogenization as well as the financial and debt crisis make the future of the nation uncertain, because it can revive or dissolve in larger communities.

Nation: A Late Political Meaning

Etymologically speaking, a nation, from the Latin *natio*, designates all those linked by birth. In modern language, the word that best expresses that original meaning of Nation is the English word 'native.' In ancient Rome, the word had no particular political meaning. It seemed even to characterize human groups with no political structures. During the Middle Ages, the word nation obtained a linguistic meaning. This explains why students at the first great European universities were regrouped in nations according to the language they spoke and sometimes even clashed along those lines!

In the Renaissance, during the process of state building, the nation again endorsed a more political bent until the French Revolution: for a long time, the nation was identified with those benefiting from a political status because they were close to the crown (the power) or were represented in those pre-democratic parliaments, from which the rest of the population was excluded (Schulze, 1996).

Only during modern times does the nation take its present and more popular meaning. The concept even absorbs almost all the different denominations characterizing political societies. Just think about the League of Nations, or the United Nations organization: this testifies equally to the might of the word and to its largely undetermined character, quasiassimilating the concept of nation with any kind of statist political organization.

From Nation to the Sociology of Nation

The nation as we conceive it today is a product of the nineteenth century, which makes it the main support of the constitution and development of modern states by using the famous 'principle of nationalities.' However, sociology took her own good time to discover the nation.

The founding fathers of sociology who carved their imprint in the nineteenth century, whether Karl Marx, Max Weber, or Emile Durkheim, were far from giving a central place to the nation in their analysis of modern society, contrarily to historians or philosophers, or even artists, who started discussions, as witnessed by diverging opinions from Renan, e Fustel de Coulanges, Fichte, or Herder. Sociology is based on 'society' whose meaning remains largely undefined. As an object research, it deals with the state or the people, but not the nation. However, these notions are often described under the characteristics of a modern nation – as without doubt by Weber in his analysis of society – but never did the concept of nation emerge.

Marx and Engels deal a little more with the notion of nation, but they consider it more as an archaic form than as a new reality pregnant with history. The next generation of Marxist authors will be more concerned by the notion, but for practical more than theoretical reasons, given the attractiveness of nationalistic slogans for the working class. We owe to Bauer, and to the 'Austro-Marxism,' a more sophisticated conceptualization (Bauer, 1907). Stalin himself tried to define exactly what he means by nation in a work where he uses its nonpolitical aspects as a basis – a restrictive one – for the Bolshevik policy of recognition of nationalities (Stalin, 1937).

As pointed out by Hobsbawm, the multiplication of works on the nation dates back mainly to the period 1968–88 when more was written on the subject 'than at any other period, even twice as long' (Hobsbawm, 1990). The concept of nation then gets a truly sociological meaning, though its definition has opened new conflicts that are still quite alive today.

However, in modern times, nation will be unanimously recognized as *the* political community that will ensure the legitimacy of the state over its territory, and moreover transform the state into the state of all its citizens. The notion of nation-state illustrates that new alliance between state and nation. Nationality will bind the citizen to the state, a bond that will be more and more tied to the advantages of a social policy in as much as the welfare state will develop.

Nobody will deny either that the nation finds its ideology in nationalism, where nation and state necessarily are intertwined into a new entity dominating all others. Nationalism will not only mark the building of nations, but also provoke the reaction of those populations who feel suffocated by this process and want to build their own nation-state. The violence of nationalism will depend on the surrounding circumstances and evolve according to the obstacles found on its way.

Where true nation-states will emerge, the nation will be the point of convergence of three historical processes. The first one is the development of states with growing sovereignty over territories whose boundaries are more and more clearly defined, and with growing autonomy vis-à-vis the non-territorial power of the Church, whose prestige and influence declined after the Reformation; this process was faster in

Northern Europe than in the South. The next step is the emergence of democracy in the aftermath of the French Revolution, transferring sovereignty from the state to the people and regrouping all citizens under principles of equality and solidarity. Finally, the development of capitalism increases communications between individuals, social homogeneity, and educational and cultural standardization, and by its very crises leads to the strengthening of states' power and the development of the welfare state endorsing an ever-increasing part of the life of each citizen.

The differences of evaluation among authors focus on the importance to be given to the ties linking the modern nation to the former 'protonational' entities. These differences concern the process of construction of those nations and the role of history in that process. For sociologists like Gellner, Hobsbawm, and Anderson, modern nation is first a rupture, even sometimes a complete one, with the past. This 'modernist' definition is at loggerheads with the definitions, called 'primordialist' by Gellner, of which the best-known representative is Smith, a former pupil of Gellner.

Two Concepts of Nation?

For the modernists, the rise of the nation can only be understood as the product of state action, and more particularly, according to the famous hypothesis of Gellner, as the result of the nationalist action of its elites (Gellner, 1983). Nationalism gives birth to nation and not the opposite. This voluntarist action is made possible, and even necessary, by modernization, that is, by the transition from agrarian society to industrial society and capitalism. Modernization destroys old social hierarchies and loyalties therein associated, and entails homogenization of language and culture throughout the state territory to allow both for mobility of workers and for mass production. Whereas agrarian societies possessed stable hierarchies where culture was linked to social status, modern society, by destroying these hierarchies, transforms culture into a kind of personal appropriation of each individual and creates a longing for harmony between individual culture and the environment: 'What automatically makes people into nationalism' (Gellner, 1999).

In that sense, nation is a truly modern invention that takes the form of an 'imaginary community' (Anderson, 1983). Indeed, nation-states have a past, at least most of them, but modernization is a phenomenon modifying so radically social practices that this past is practically irrelevant for the construction of modern nations. Or, at best, it is so remolded that it loses any true historical characteristic. One example, pointed out by Gellner, of a nation created *quasi ab nihilo* is the case of Estonia. Whereas that nation has no past to speak of, its elites managed to give it life, to develop a distinctive culture, and to impose it among the other nations. In this manner, Estonia is an ideal type of a nation in the modern sense of the word.

At the opposite end, for the primordialists, the development of the nation-state, and therefore of the nation, is understandable only through analyzing its historical roots. Smith calls this approach 'ethno-symbolist.' One cannot but study the role of myths and prenational symbols in order to distinguish nationalisms from one another, and above all to explain why nationalism will be virulent in one case and not in the other (Smith, 1986). The existence of competing nationalisms in Greece cannot be understood if one loses sight of "its dual heritage of byzantine imperial orthodoxy and classical democratic antiquity. Modernism tells half the story," writes Smith. But Gellner answers that "if it tells half the story, that is enough for me!" (Smith, 1999; Gellner, 1999).

In this perspective, Hroch offers an authoritative developmentalist typology of national movements. These movements evolve in three phases. First is that of purely cultural, linguistic, or folklore-related aspirations. Second is that of the rise of militant groups promoting the 'national idea' and starting social trouble around the national theme. Third is one that finds spreading support among the masses for the new national aspirations. The transition from the second to the third phase will often be marked by a 'nationally relevant conflict of interest' (Hroch, 1985).

What are the factors prior to the nation that can legitimize its rise? The most frequently mentioned ones are language and religion. Language will be particularly important as a factor when it has been threatened or has been a basic mode of identification. This is the case, for instance, in Belgium, where Flemish nationalism concentrates in a language that has been the object of assimilation by a dominant language (Delfosse, 1994). However, language is not necessarily the essential legitimizing source of nationalism and nation. The French Revolution does not establish a nation-state on a linguistic basis: the French language is deemed indispensable to proper revolutionary ideals, but is not considered an exclusive and sacred good. It is a kind of tool of citizenship and, through it, of the nation. Completely different is the importance of language in the creation of the German or Italian nation-state. Before its founding, language was the only unifying factor of scattered populations and therefore took a more affective meaning than in the French case.

Another factor of importance is religion. The Reformation played a key role in the rise of modern nation-states by emancipating them from the power of the Church, on the spiritual level as well as on the territorial level. However, for a sociologist like Rokkan, religious criteria seem of less importance than language. For him, language has a more defined territorial characteristic than religion and the notion of nation is linked strongly with a territorial foundation. That last factor is the decisive one: there is no nation without territorial identity. Therefore one must call on intricate processes, ethnicocultural, religious, linguistic, and politico-administrative factors that can go back a long way (Flora, 1999).

Other determinants could be named here, but it seems almost impossible to find a unique definition of the objective elements that would characterize the nation. The primordialist school would tend to offer a specific approach of the creation of each particular nation. Indeed, nations have been built on criteria much too different to allow for the constitution of a 'hard core,' even if modernization in each case has added its own particular homogenizing effect.

This controversy between modernists and primordialists, that is, between those for whom nationalism created the nation and those who look for links between nationalisms and preexisting national characteristics to explain their different development and intensity, is far from ending in the

sociological literature. For Hroch, these two approaches are not necessarily incompatible, for there is interaction and not dominance between nation and nationalism (Hroch, 1999). In this perspective, we can borrow Disraeli's lapidary expression that applies so well to national construction: of art and time.

The Future of the Nation

Since the nineteenth century, the world has become one of nations whose number is ever increasing in the framework of the United Nations. Some of them have been the result of Europe's export of her own model of nation-state through colonialism. That model, despite its artificial character, has been largely 'instrumentalized' by movements of national liberation in order to consolidate their state authority (Badie, 1992). National demands inside even the best-established nation-states, directed against their domination (the so-called 'internal colonialism'), never stopped and the desire for a state sometimes led to ruptures, and sometimes to reorganizations of states on the regionalist or federalist models.

Today, however, nobody can deny that changes are at work on a global scale that put into jeopardy the future of the so-called modern nation. 'Mondialization' and most of all 'globalization' send a major challenge to most of the nation-states. Whereas nation-states drew most of their power from their quasiabsolute control over their territory, and particularly over their national economy, globalization deprives them increasingly of their real competences as well as their resources, while severely affecting their legitimacy, even though this globalization is on a 'shifting scale' according to different domains. At the same time, that evolution has been facilitated largely by the collapse of the Soviet Empire, which, however, gave free rein to an unexpected 'pent-up nationalism.'

The cultural melting pot combined with the prevalence of English as an international language and the mixing of populations and cultures, be it on the virtual level with Internet or in reality with population migrations and immigration to rich countries constitutes an evolution whose effects are particularly difficult to integrate in homogeneous cultures typical of classical nation-states.

Habermas states the problem in terms of a relatively simple alternative, at least on the politicoeconomic level: either the most threatened nation-states will withdraw in neo-protectionist 'tentatives' bound to fail, or they will try to reach 'the same level as the markets,' which entails their entering some sort of supranational integration. The world of culturally homogeneous nation-states will fade away, leaving the stage for new mixed entities, particularly on the level of cultural homogeneity (Habermas, 2000).

The big question of whether the process of globalization will dissolve nation-states into new and necessarily pluralistic entities, or will give rise to renewed nationalistic demands challenging it, or, yet, whether the two phenomena will go hand in hand, remains largely open, even if what can be observed goes in the sense of the third alternative. In this sense, the European Union represents the most advanced form of supranational integration in the world. Since Europe is also the cradle of modern nations, an analysis of the processes taking place there is of the utmost interest for the future of the nation.

During the 1990s and at the beginning of the twenty-first century, for most analysts, this double-faced process was supposed to continue without seriously threatening the advancement of European integration, which still profited from the 'permissive consensus' of the national populations, even if it was slowly declining. Partisans of European integration regarded with great astonishment and even with real fear that the results of the referenda about the Constitutional Treaty were clearly negative in France, the Netherlands, and Ireland (2005). The effect was a crisis in the development of the integration process and the discovery of an antagonism deeper than anticipated before between Europe and important segments of national populations. The financial crisis of 2007 and the following crisis of the public debts of nation-states did not help at all to reduce the gap – even if the only real solution of this latter crisis may lie in a more federal union, a solution which is not supported until now by most of the nation-states. It seems, on the contrary, that, for the present time, most of the populations prefer to find solutions in the safety net offered by their own states. Does this signal mean a revival of the old nationalism of the European peoples? Not exactly – with the exception of some extreme populist movements – but rather a 'sovereignist' (*souverainisme* in French) attitude, which can be conceived as a form of functional nationalism, seeking more protection for maintaining their privileged situation, on social and political grounds, without having to share their resources with neighbors, rather than an aggressive attitude vis à vis the other nations perceived as enemies. It is more than a kind of 'banal nationalism' in the sense of Billig (Billig, 1995), but not very much more.

One can conclude that the future of nations is uncertain. They are subject to contradictory forces. Nations are affected by the globalization processes, producing for mixed populations a new standardized culture, which weakens the importance of territories and consequently of nations and national cultures. But this evolution can also trigger a reaction of these national cultures, with very different kinds of effects, from boosting national pride, but not in an antagonist way, to attitudes close to ethnocentrism and beliefs in 'clash of civilizations' theories (Duchesne and Frognier, 2008). At the same time, as far as Europe is concerned, it is difficult today to predict whether the European Union's efforts to manage the present crisis will succeed, with the implication that national egoism of the rich countries will have to be tempered, or if the European integration process will come to a halt or even will return to earlier, lower degrees of integration. A Pyrrhic victory for the European nations?

National Account Systems

Abstract

This article addresses the historical development of the System of National Accounts (SNA) as a process of negotiating and struggling about concepts and definitions. It starts with an explanation of the idea of the SNA, presents briefly some of its predecessors and shows its chronological development in the twentieth century, national differences in the adoption of the SNA, and the main cleavages in the international harmonization process. Then, it goes deeper in the revision of the most recent SNA and, finally, shows its political relevance.

Introduction

The System of National Accounts (for short, SNA) is the most comprehensive tool that aims at describing and analyzing economical activities within a defined geographical area of a defined time period. It is also used to forecast economic growth and produces the perhaps most visible and powerful scientifically produced number: the gross domestic product (for short, GDP). In the second half of the twentieth century the SNA became a powerful tool for policy making and economic planning. Actors on financial markets are also geared to the quarterly published data produced in the framework of SNA (Kenessey, 1994, p. 1). The SNA is "the internationally agreed standard set of recommendations on how to compile measures of economic activity in accordance with strict accounting conventions based on economic principles. The recommendations are expressed in terms of a set of concepts, definitions, classifications and accounting rules that comprise the internationally agreed standard for measuring such items as gross domestic product (GDP)" (SNA, 2008). The SNA gives a systematical overview of how income, production, and distribution of goods and services are related to each other and how they are distributed to consumers, businesses, governments, and foreign nations and considers how taxes and social transfers influence the flow of capital. The SNA is intended for global use and it should be flexible enough that countries of different levels of development can implement it. It is a tool for policy making, for statistical and scientific use, and it is the main information basis that informs a society about its own economic development and the development of other societies. It should provide an overview of the overall economy, its main sectors, and their relationships to each other and should unify the view and the epistemic use of economy on a global level. When economists describe the SNA they tend to use metaphors like the "bird's eye view on the economy" (Gilbert und Jaszi, 1944) indicating that it provides a distant view on the economy, or they use the image of a "radiograph of the economy" (Frentzel-Wagner, 1959), respectively, a "tool for [economic] diaphanoscopy" (Nützenadel, 2005, p. 90) to point to the SNA's ability to look 'into' the economy.

In 1939 Joseph A. Schumpeter wrote about the national income, the predecessor of SNA, that "[t]he familiar difficulties which we all experience in defining National Income are of course due to the fact that it is not a technical term wedded to one definite use but a word of common parlance that is loosely used for a great many purposes which cannot be served equally well by a single definition" (Schumpeter, 1939, p. 561). In contrast to costs that can be measured by prices, the total output in terms of physical entities is a "figment which […] would not as such exist at all, were there no statisticians to create it. We seem indeed to be faced by a meaningless heap." (Schumpeter, 1939, p. 484). Considering Schumpeter's argument, the history of the SNA consists of at least 350 years of lasting struggle about this 'common parlance' and about giving the statistical 'heap' a meaning by defining what counts as economic activities and how they are grouped. The main problem in this struggle is to negotiate and to define accounts and their corresponding economic activities. It is this struggle about the "accounting structure" (Vanoli, 2005, p. 109) that employed a good number of economists.

At least four of them were awarded with the Nobel Prize for works on national accounts: Jan Tinbergen in 1969, Simon Kuznets in 1971, Wassily Leontief in 1973, and Richard Stone in 1984. Stone and Kuznets were decorated by the Nobel committee explicitly for their "pioneering research around national accounting systems" and for their contribution to the development of "methods for calculating the size of, and changes in, national income" (www.nobel.se, last update 31.12.13.).

The idea to measure a nation's total economy and to find out the economic strength of a whole country goes back to the seventeenth century, "a determined antiquarian can almost always find an earlier example, often by recourse to China" (Galbraith, 1980, p. 75). However, modern, systematic, and frequent compilations of the national product were set up in the 1930s, institutionalized in the 1950s, and internationalized in the 1990s. The struggle about definitions and standards is not over at the time of this publication. Still, it has calmed down and is regulated in controlled paths.

Predecessors

The first attempts to compile an overview of the economy as a whole were made by William Petty (1623–1687) in the seventeenth century. In his book from 1662 titled *Political Arithmetick* he expresses social and economic activities in quantitative terms. He was deeply concerned with the creation

of more reasonable methods to fix taxes. In his work he considered three accounts of income (land, estates, and work) and one for expenditures (summarizing clothes, food, housing, and all other necessaries) and the national income was a simple addition of the three income accounts (Studenski, 1958, p. 15; Vanoli, 2005, p. 4). Following Petty's work, a number of authors were engaged with compiling a National Income, such as Gregory King (1648–1712) (Studenski, 1958, p. 16) in England, or Pierre de Boisguillebert (1646–1714) in France, who tried to measure the economic strength of his country to compare it with others.

Several works followed and began to specify national income – the struggle about a "common parlance" (Schumpeter, 1939, p. 561) began. One of the problems was how to value goods. Thomas R. Malthus (1766–1834) argued to value them by market prices, and Adam Smith (1723–1790) wrote about 'natural prices.' Other discussions were about the relationship between national income and welfare. Arthur C. Pigou (1877–1959), for example, invented the notion of 'national dividend' and defined welfare to be a consequence of a high 'national dividend.' Another one was the question what should be included in the national income.

Alfred Marshall is called to be the first one to include not just products but also services and valued them by market prices (Lepenies, 2013, pp. 39–46). In contrast, the French physiocrats even limited the national income to agricultural products. Another milestone was Francois Quesnay's (1694–1774) *Tablau Economique* because he emphasized on the *flow* of goods and money between social groups, that is "an anticipation of what was done in the twentieth century" (Vanoli, 2005, p. 12).

Early attempts to estimate the national income were limited by the access and reliability of data. The "enlightened amateurs" (Vanoli, 2005, p. 13) of the early days tried to gather the biggest possible amount of data and had to be very creative and flexible when compiling accounts and the main aggregates. Most of the estimates about national income included material production and material goods, the trade with these goods and transportation. And there are some good reasons to assume that the motivations were not just in public interest but also political: to pay less taxes, to make the own social class stronger, to show that one's own country is superior to others.

The SNA in the Twentieth Century

The early attempts of compiling the national income were noninstitutionalized initiatives of private persons who had quite diverse motivations to conceptualize and represent economies as a whole (see e.g., the story of Roger Babson in Friedman, 2014). At the beginning of the twentieth century this changed twofold. First, the organizational frame of economic statistics changed from private to government and increased in quality (Speich Chassé, 2013, p. 96). The end of the "hero phase" (Vanoli, 2005, p. 15) started when Canada, as the first country worldwide, began to regularly publish estimates of its national income. That was the time when economic statistics got out of the hands of amateurs and private thinkers and administrative units took over, began to gather data and compiled economic aggregates. The new organizational frame is a result of the economic crisis in 1929 when governments began to think about how to intervene in economic development (Lepenies, 2013, p. 122). It is also connected with John M. Keynes' general theory that established the concept of macroeconomy and provided the theoretical basis to end a laissez-faire policy (Kurabayashi, 1994). And it was also the result of the needs of a war economy and the demand for an epistemic system that documents and legitimates governments' actions.

Second, there was a conceptual shift. The perspective changed from the emphasis of a nation's income to the sum of the production of a nation's economy. The former conceptualized a nation's economy in terms of capital and incomes of businesses and individuals. The latter emphasizes products of economic sectors, summarized in accounts. In the first third of the twentieth century, several authors had the idea to extend double-entry bookkeeping and accounting from a business level to the whole economy. Irving Fisher, Morris A. Copeland, and Robert F. Martin in the United States; André Vincent in France; Ferdinand Grüning in Germany; and Ed van Cleff in the Netherlands suggested different ways to think about national economies in terms of national accounts (Vanoli, 2005, pp. 16–17).

It might be arbitrary to identify one single starting point of the international spread of the SNA. However, Richard Stone's and James Meade's paper from 1941, with their suggestions on how to structure and compile an SNA, is widely accepted as the historical starting point of an international development of adoption and harmonization of the system national economic accounts as well as discussing the problems and limits of a unique SNA (Meade and Stone, 1941; **Table 1**).

This article landed on fertile soil. Even in 1939 the League of Nations had the idea to compare countries by a standardized scheme and started to collect data – but World War II stopped

Table 1 Milestones of the SNA-Development

1941	Richard Stone and James Meade publish their paper on national accounting
1945 (Sept)	United Kingdom, USA, and Canada meet to discuss possible ways to harmonize their national accounts
1945 (Dec)	The League of Nations meet in Princeton where Richard Stone presents his system of national accounts (report published in 1947)
1949–1950	OEEC simplified system
1952	OEEC standardized system
1953	UN published first version of SNA 1953, revised in 1960 and 1964
1968	UN published SNA 1968, preparation 1964–1968
1970	European System of Accounts (ESA), preparation 1964–1970
1971	UN publishes the Basic Principles if the System of Balances
1977	Comparisons of the SNA and the System of Balances
1989	UN publishes a revised version of the System of Balances
1993	UN, IMF, World Bank, OECD and European Union publishes the SNA 1993
1995	European Union publishes the ESA 1995
2008	UN, IMF, World Bank, OECD and European Union publishes the SNA 2008
2010	European Union publishes the ESA 2010

this attempt. Furthermore, in September 1945 Canada, Great Britain, and the USA organized a tripartite conference to negotiate about the possibilities of a common standard about national income estimates and about the establishment of a common SNA (Vanoli, 2005, p. 24).

In December 1945, Richard Stone had the chance to present the ideas summarized in the paper mentioned to a conference organized by the League of Nations in Princeton. As a result, this conference published a report titled "Measurement of National Income and the Construction of Social Accounts" that was fully accepted by the United Nations in 1947. Though its status is challenged – Vanoli (2005, p. 26) argues that it was even a technical paper, Bos (1994) treats it equal to the all SNA recommendations – this report was a hallmark of the international process of the harmonization of the SNA.

The 1947 report was the basis of several follow-up papers. The OEEC, established in Paris in 1948 to organize the recovery program in Europe, published a 'Simplified System' in 1950 and in 1952 the OEEC's 'Standardised System of National Accounts' came out, closely followed by 'System of National Accounts and Supporting Tables,' published by the United Nations. Until 1965 the OEEC compiled its own system of accounts parallel to the United Nations. The main motivation for that was to establish comparable indicators to estimate economic wealth and growth rates of the countries that profit from the Marshall plan. As the economic recovery in Europe succeeded there was no more use for two parallel SNAs (Vanoli, 2005, pp. 89–90).

The SNA was generally revised for several times. On average, a SNA has a tenability of about 18.5 years. General revisions were made in 1968, 1993, and 2008 and include completely new accounts structures. For the first time in 1970, the 'European Communities' published their own accounting system called European System of National Accounts (for short, ESA) with a time gap of 2 years to the SNA (Vanoli, 2005, pp. 91–98). So, whereas the OECD stopped making its own system, the European Union is still compiling its own system of accounts which is a revised and adapted derivate from the SNA.

(Inter-)National Differences

In the 1950s only a small number of member states of the UN completely implemented the recommendations of the SNA 1953. The basic system of accounts was similar in Western countries but differentiated in details. They had in common to emphasize the production side of the accounts and the amount of the GDP (Lepenies, 2013, p. 159). At the same time a global process of harmonization of the national accounts structure started – a process that is not completed nowadays. In Western Europe, the Economic Cooperation Administration (ECA) that coordinated the financial aid for the economic recovery played a crucial role for the standardization of the SNA. It aimed at estimating the economic potential of European countries after World War II to define standards for economic aid. The ECA founded the OEEC and asked it, together with the 'National Accounts Research Unit' at Cambridge, to develop a simple but standardized system of accounts for European countries and trained European economists and administration staff to gather data and to use the account system. Thus, the US help to recover European economies was also a way to harmonize the SNA.

However, the harmonization process was not this successful in other parts of the world. The SNA was not adopted by all the countries at the same speed and in the same manner. As it was a Western concept, mainly developed in Great Britain and the United States, the Soviet Union was skeptical to implement it and went its own way, called 'Material Product System' (MPS) with the main difference that only material products add value to the economy. A predecessor of the MPS was an index for the industrial output compiled by Nikolai D. Kontradieff. It was available for every year until 1885 (Gerschenkron, 1947, p. 145). After the breakdown of the Soviet Union, Eastern Europe implemented the SNA 1993 and so brought its internationalization a step forward (Vanoli, 2005, pp. 100–101). China used the MPS and the western SNA in parallel between 1985 and 1992. Afterwards, China changed to the use of the SNA 1993, and the MPS disappeared globally together with the USSR.

The United States played an ambivalent role in the harmonization process (Speich Chassé, 2013, pp. 149–45). Although US economists and organizations were leading in the conceptual foundation of the SNA, the US administration never implemented the system changes and built its own account structure. The SNA 2008 was the first one completely used by the United States. And USA's commitment in the revision processes was quite different in the 1960s and the 1990s. Though, they were deeply engaged in the development for the 1993-SNA, they never completely implemented it for reasons of law specialties and personnel changes in the administration staff (Vanoli, 2005, p. 125).

Germany was never a driving force in the development and internationalization of SNA – Reich calls it a "latecomer in national income estimating compared to other countries" (Reich, 1994, p. 148). Although there are some early attempts to analyze economies as a whole, German economists especially from the 'Historical School' denied any approach to estimate national income in the 1920s (Reich, 1994, p. 149; Studenski, 1958; Speich Chassé, 2013, pp. 67–80). In the first decade after World War II political actors were skeptical about the SNA as a whole. It was ill-reputed as a tool of illegitimate state intervention and did not fit into the German postwar economic policy. In contrast to that, France very early recognized that SNA was also the "accounts of power" (Nützenadel, 2005, p. 102).

In the 1970s many countries in the southern hemisphere started to implement the 1968-SNA. It was France who helped many third world countries to get systematically informed about their economies. Until today, there are controversies over the SNA's role in less developed countries' economies (Vanoli, 2005, p. 104).

The Main Cleavages during the Process of Harmonization

In his Nobel prize lecture, Richard Stone reported that in the 1950s there was just a small number of statisticians who did fully understand the ideas and conceptions of the SNA. Thus, there were less discussions when nations tried to harmonize the accounts. The duration of the discussion process and the complexities of the system increased with the number of well-informed participants (Lepenies, 2013, p. 132). Still, it is not just the higher number of actors involved, but also their

unclear roles, and their different national backgrounds with different ways to decide on a national level (Vanoli, 2005, p. 87). The number of countries and organizations involved in the revisions of the SNA increased enormously during the twentieth century as did the size of the system that grew from 57 pages in 1953 to 722 pages in 2008 (with a peak of 838 pages in 1993). This growth of about 1200% shows the complexity of an SNA composed for global use.

What are the main conflict lines that can be identified in the history of establishing global conventions for the SNA? Mainly, there is a continuous discussion about what economic activities are and which economic activities should be included in an estimate covering the whole economy. A second general question is, what role the state should play within the concept of the national income and the SNA. Connected to this problem, there is a broad discussion about the aims of economic activities. Is it only to produce more goods or is it to make a society happier? With the focus turned from national income to the economical production side, a further conflict came out: Are the aggregates (e.g., the GDP) or the accounts, i.e. the basis of the aggregates, more important for an SNA (Vanoli, 2005, p. 28)? A quite early discussed problem is the idea to use national income statistics and national accounts to compare countries (e.g., Rosenstein-Rodan, 1944). This question is still open as the analysis of differently structured economies and different natural resources using the same theoretical approach is often criticized (e.g., Morgan, 2011). Gerschenkron's (1947) attempt to analyze the economic growth of Russia until 1885 is an impressive document of the problems to compile and to compare a less industrialized and politically planned economy with capitalistic economies.

Conventional Changes in the SNA

The frequent revisions of the SNA show its conventional character. Some of the recent changes of the ESA exemplify that. The ESA 2010 replaces the one from 1995. It is a general revision and will become res judicata in the second half of 2014 in all member countries of the European Union. In contrast to the SNA, the ESA is obligate to all members of the EU. Both are consistent in their basic concepts, but the latter includes further and more precise rules to gather and compile the data. This is necessary because the ESA is the basis for the calculation of the contributions to the EU budget, it compiles the ratios of deficit and debt and thus, it is a tool to keep the member states under surveillance. This makes the ESA a politically relevant system. In all member countries a revision of the accounting system makes a deep recalculation of the data sets necessary to keep the data from the past comparable with present and future data. Every revision produces costs and needs much organizational and computational work. So, why is it necessary to revise the SNA regularly? These revisions enable the SNA to represent recent economic and social developments adequately and to bring macroeconomic statistics in line with the recent economic environment and the needs of the users (Statistisches Bundesamt, 2013).

There are two kinds of revisions: first, there are technical and methodological revisions most users of the SNA do not notice, for example, new grouping conventions for sectors of economic activities. These revisions do not change the aggregates. Second, and more interesting to the public are changes in the conceptualization of the accounts. Normally, these changes are reactions to developments in economy and society. One of the main changes of the ESA 1995 may exemplify that. Whereas the ESA 1995 defined costs for Research and Development as current expenditures, the ESA 2010 treats them as investments. Especially in knowledge-intensive and digital economies these investments are important and therefore they should be part of the economy's output. The same is with the treatment of military goods and weapon systems. They will also be treated as states' investments in the future. Actually, both reclassification will influence the GDP. Preliminary estimates show that all changes between the systems of 1995 and of 2010 will increase the GDP +3% for the United States and +2.4% for the EU. And they will also increase the analytical capacity of the balance sheets and their fitting to reality. Another change regards the treatment of the flow of stocks and financial products through the world as a reaction to globalization of the economy (SNA, 2008, p. xlviii; see also Vanoli, 2005, pp. 109, 124). And the revision will also consider new data sets to make the accounts more precise and up-to-date, e.g., the statistics of people in paid labor, the data about where and how inhabitants live.

The Political Nature of the SNA

The struggle about definitions and the classification of economic activities are not mere academic questions or nerdy nitpicking. Besides, it is also a political conflict. Even in the early attempts of compiling national income estimates there were actually political conflicts behind the scientifically discussed questions. William Petty's concepts and computations aimed at showing that tax charges were distributed uneven between the classes. He argued that income from labor was higher than it was supposed to be and that it represented a higher percentage of the national income than it was supposed to. Petty aimed at showing that the impact of his own class was smaller and therefore, tax charges should be smaller (Lepenies, 2013, p. 35). Another sign of the political nature of National Income and SNA estimates is that many of the early authors were offended for political reasons. Their books were forbidden and destroyed or authorities decided to keep them secret because of both, the critical topic per se and because of the conclusions the authors draw from their data (Vanoli, 2005, p. 5).

An example from a long-lasting struggle in the 1930s and 1940s shows that different economical classifications lead to contrary political results. In Simon Kuznets conception of the national income the state does not play a crucial role. When he spoke about the national income he meant the 'national income paid out,' that is, the amount of money available to every household. For Kuznets, expenditures for armament, infrastructure, and transport (the costs for the 'economic civilization') are 'evil necessary' and decreases the whole amount of national income because the money spent on these goods is no more to the private households' disposal. For Kuznets, the states' expenditures decrease the national income (Kuznets, 1933). Before the United States was engaged in World War II, the Office of Price Administration and Civilian Supply

(OPACS) argued vehemently for an increase of the war budget but did not succeed with that political position. One of the reasons was that, using Kuznets' conception, it would decrease national income. Only a Keynesian approach could solve this problem. It argues the other way around: the states' investments increase the national income as they are also a form of production of goods, no matter who produces them for what.

The work of Meade and Stone was highly influenced by Keynesian ideas and, through a personal network between Simon Kuznets, Milton Gilbert, Richard Stone, and Richard Gilbert, the cousin of Milton, these ideas entered the 'Defense Economic Section' in the OPACS. With this classification of economic activity, the higher states' investments do not necessarily decrease national income but, actually, increases the 'social product.' The conceptual turn from income to product, that also was the reason for the break up between Simon Kuznets and his scholar Milton Gilbert, shows that different economic theories lead to different types of classifying economic activities leading to how the states' activities are handled and thus, how the state can legitimate its actions. It's classification, stupid! (Lepenies, 2013, p. 100)

Another historical struggle about how to measure economies in total is the one between the East and the West during the Cold War. The battle between two different political systems was also fought on the field of SNA definitions. In 1961 the Yugoslavian economist Branko Horvat reported the Soviet system of accounts, called Material Product System (MPS), and quotes a leading soviet economic textbook: "In Socialism, as in any other system, total social product is created by the labour of workers in branches of material production. Along with manual workers, brain workers (scientists, engineers, etc.), engaged in branches of material production, participate directly in the creation of material wealth. [...] Workers engaged in the non-productive sphere (state administration, culture, welfare, medical service), do not create material wealth. Nevertheless, the labour of workers of non-productive branches is indispensable for socialist society, for material production it represents socially useful labour" (Ostrovitjanov und Vasil'evič 1959 cited in Horvat, 1961, p. 234). Horvat argues that the Soviet definition fits better to measure 'economic' and 'military strength' and also "social welfare" (Horvat, 1961, p. 235) than the American one because it distinguishes between goods and "social waste" (Horvat, 1961, p. 238), e.g., weapons. 'Social waste,' Horvat says, may increase the American social product but would not make its society better. The definition differs from the concepts of both Kuznets and Stone and (Vanoli 2005, pp. 100–101) claims that it did not fit the reality but is the product of ideology.

A recent political debate about the significance of the SNA and especially about the aggregate in the public focus, the GDP, was initiated by the former French president Nicolas Sarkozy. Together with prominent economists he built a commission "to identify the limits of GDP as an indicator of economic performance and social progress" (Stiglitz et al., 2010, p. 7). Quite critical, it recommends to differentiate between mere economic measures, the peoples' well-being, and the evaluation of the sustainability of both. At about the same time, the German parliament built an enquete commission with economists and members of the parliament on the same topic. In April 2013, it published its final report where it agrees that GDP cannot be the only indicator that informs about the condition of and recommends splitting it up to three dimensions: wealth, social development, and ecological factors. Until now, the GDP is still the central economic indicator in political debates in both countries.

Conclusion

In the beginning of the twenty-first century the SNA is central for both economics and economic policy. The history of the SNA is not just one of struggles about scientific classifications and of the competition between political systems. It is also an impressive success story of a scientific concept as it becomes institutionalized in more and more countries and it is dominating the way how societies think and know national economies as well as global economic relations. The main aggregate of the SNA, the GDP, is something like a unique index in the scientific world as it gives a simple and accepted answer to the complex question, how a whole economy is doing. The criticism that is passed on the SNA will not calm down. Still, at the moment, there is no evidence that another economic concept will replace the SNA in the global discourse.

Abstract

National character is an expression which describes forms of collective self-perception, sensibility, and conduct which are shared by the individuals who inhabit modern nation-states. It presupposes the existence of psychological and cultural homogeneity among the citizens of each country, as well as the idea that each nation can be considered a collective individual, with characteristics analogous to the empirical individuals who are its inhabitants. The noun *character* seeks to describe a universal aspect of social life – an internal dimension to the existence of individuals and an external one, observable through collective behaviour. The adjective *national* situates this universal aspect of social life in the specific context of those social units we call nations. Social theory interested in understanding the social force of feelings of national belonging has turned once again to this expression, which was first formulated in Europe during the second half of the eighteenth century. What distinguishes this trend is the fact that there is no attempt at attributing any theoretical status to national character; instead, it is more concerned with it as a practical category used in the discourse and action of the social agents and groups. The aim of this article is to summarize the genealogy of the expression and to discuss its current heuristic value.

National character is an expression which describes forms of collective self-perception, sensibility, and conduct which are shared by the individuals who inhabit a modern nation-state. It presupposes the existence of psychological and cultural homogeneity among the citizens of each country, as well as the idea that each nation can be considered a collective individual, with characteristics analogous to the empirical individuals who are its inhabitants. The noun *character* seeks to describe a universal aspect of social life – simultaneously an internal dimension to the existence of individuals and an external one, observable through collective behavior. The adjective *national* situates this universal aspect of social life in the specific context of those social units we call nations.

Since it was first formulated in Europe during the second half of the eighteenth century, the idea that the inhabitants of each nation possess psychological and cultural characteristics in common, which confer upon them identity and distinguish them from others, has always been a part of the ideology and practice of nationalism. Hence its double status, being simultaneously a descriptive and a prescriptive expression. On the one hand it describes communities of custom, forms of being and feeling, on the other it serves to make legitimate claims for sovereignty and forms of political action. One refers to the essence of each people or nation, the other supposes that collective action can serve to favor or even to mold the national character of a political community in the making.

During the 1940s and 1950s, the expression national character gained scientific legitimacy within the so-called North American anthropological school of Culture and Personality, to the point of designating an object of study and a university specialization: national character studies. From then on, it has been at the center of various academic controversies, where many have questioned its theoretical status, attributing its scientific shortcomings to its close relationship with the essentialism characteristic of nationalist ideologies. Yet recently, social theory studies interested in understanding the social force of feelings of national belonging and the new forms of nationalism have turned once again to the expression. What distinguishes this trend from national character studies is the fact that there is no attempt to attribute any theoretical status to the expression; instead, current studies are more concerned with the expression national character as an object, a practical category used in the discourse and action of the social agents and groups which one seeks to understand (for an argument in favor of the study of the categories of national identification as 'practical categories' see Brubaker, 1996).

National Character and Nation-states

Questions dealing with national self and unself have been historically associated with the origin of nation-states and with international relations. While the processes leading to the emergence of new nation-states served to substitute older national elites for new ones, redefining the borders between countries along the way, the belief in the singularity of *one* national character, also demanded the recognition of a plurality of national characters from which it became necessary to differentiate.

One of the most detailed examples of the relationship between we-ideals and we-images in the formation of nation-states can be read in Norbert Elias' studies of the Germans (see Elias, 1994, 1996). Discussions concerning 'national character' in Germany emerged within the context of an encounter between new intellectual figures and a public capable of understanding and identifying with them. The poetry and philosophy of the second half of the eighteenth century (authors such as Herder, Schiller, or Goethe and movements such as *Sturm und Drang*) celebrated the ethic and aesthetic community grounded in the concept of *Kultur*, whose principal, distinguishing element was the use of the German language in opposition to the French spoken in the German courts by the social elites of the time. One century later, when the heirs to this intellectual tradition, backed by sections of the military and the old imperial nobility, established themselves within the German nation-state, words such as *Kultur* (alongside words

such as *Volksgeist* and *Zeitgeist*) had already become 'nationalized,' thus designating the we-ideals and the we-images of social groups in a larger scale and describing forms of collective self-perception and the 'German National Character.'

The diffusion of the nation-state as a means for organizing social life (see, for example, Balibar, 1991 [1988] and Anderson, 1983) brought about similar processes in other areas of the world. At the start of the twentieth century, and particularly after World War I, the end of the old Empires served to reinvigorate nationalist ideologies in central and eastern Europe. Ideas about the national character of the Hungarians, Poles, Czechs, Romanians, Croats, and Serbs began to inform the unification policies of new states. By then, however, debates about 'national character' were no longer confined to European intellectual circles. In America too, the most renowned authors were those who succeeded in describing the traits of the 'spiritual community' to their compatriots, who then recognized themselves in these. Their texts and ideas served as a guide for state politics, spreading beyond the literate elite and onto other social groups in the process of nation-making (particularly through the expansions of literacy and the school system). In Spanish-speaking America one of the best examples may be the Mexican writer Manuel Gamio, author of well-known statements on what it means to be Mexican, centered on the relations between the descendants of pre-Hispanic peoples and the Spanish (Gamio, 1916). In Portuguese-speaking America the best example is Gilberto Freyre, remembered as the author of one of the most influential representations of Brazilian national character, based on the idea of miscegenation between Whites, Blacks, and Amerindians (see Freyre, 1933).

Among the many similarities between the two authors is the fact that during the 1920s both resided in the USA and studied under the German anthropologist Franz Boas at Columbia University. Boas is largely recognized as one of the intellectual fathers of the Culture and Personality school which later served as an inspiration behind national character studies (on the Culture and Personality School see the articles collected in Stocking, 1986).

National Character Studies: A War-time Anthropology

The Culture and Personality School was marked by two main ideas. The first, based on the concept of primary socialization, sought to explain the relationship between types of culture and types of personality based on the experiences of childhood (see Mead, 1928). The second, centered around the idea of patterns of culture, intended to describe and psychologically profile cultural configurations and the types of personality associated with them: each culture, although made up of fragments from different origins, developed a specific 'style,' capable of bringing about its unification as a synthetic totality and, at the same time, distinguishing it from other cultural units (see Benedict, 1934). Even though the relationship between the concept of patterns of culture and the theories concerning German national character were very explicit (in her books, for example, Benedict mentions Dilthey and Spengler), the use of the concept was primarily restricted to primitive or simple (i.e., non-national) social forms, the traditional object of anthropological inquiry.

The use of these ideas in attempts to understand cultural configurations and personalities within national communities was, in fact, closely tied to the experience of the extreme and intense form of international relations which is war. For it was immediately after North-American intervention in World War II that a group of anthropologists (foremost among them were Gregory Bateson, Ruth Benedict, Geoffrey Gorer, Clyde Kluckhon, Ralph Linton, Margaret Mead, Rhoda Métraux, and George P. Murdock) became involved with the Office of War Information, intending to place the theories and methods of social anthropology at the service of the war effort. Its first goal became to produce a statement about national character which would help maintain the high morale of Americans during the conflict. Soon afterwards, its activities turned towards attempts at understanding allied and, specially, enemy nations.

The end of the war led to what would later be considered the most convincing evidence of the efficacy of national character studies. After Japan's surrender, the American government decided to maintain the Japanese emperor in power, as had been recommended by the Office of War Information in a memorandum signed by Gorer. This helped to ensure stability in postwar Japan and to guarantee that, despite Hiroshima and Nagasaki, a new state of equilibrium between the two countries could be established. This concurrence between US foreign policy and the anthropological analysis of the place of the Emperor in Japanese culture has been cited ever since as a fine example to the kind of 'applied anthropology' which national character studies allows.

But it was in the early 1930s that anthropological solutions to 'practical' problems began to be elaborated in the USA. Up until World War II, applied anthropology had been a matter for internal affairs, aimed at solving problems derived from American cultural and social diversity. In shifting the field of applied anthropology to external affairs, national character studies crossed a significant threshold in the history of anthropology. According to the division of labor established between the disciplines at the time, anthropology had been confined largely to the study of social forms different from those of the observer, and thus different from national societies and cultures. Now, for the first time, anthropologists began to deal explicitly with nation-states as an object of study. The discussions which then followed went beyond the concerns of anthropologists alone, and began to interest all those who sought to comprehend national forms of social and cultural life (for an analysis of the relations between theory and politics in national character studies, see Neiburg and Goldman, 1998).

First the USA and the Americans, then Japan and the Japanese, Germany and the Germans, Great Britain and the British; a little later (already in the context of the Cold War) Russia and the Russians, Poland and the Poles (see, for example, Gorer and Rickman, 1950) – all came to be treated as cultural worlds susceptible to analysis on the basis of the same categories used in the study of so-called 'simple societies,' those to which, until then, the majority of anthropologists had restricted their attention. Frontiers between countries were treated as cultural, and cultural frontiers were treated as national, thereby delimiting new objects for analysis. The context of war and of conflicts between nations demanded, however, a methodological 'development': 'studies of culture at a distance' (see Mead and Métraux, 1953; Mead, 1953). Anthropologists, prevented

from carrying out the traditional task of prolonged participant observation in the field, would now interview immigrants, analyze novels or films made in other countries, or examine media productions, so as to reach those cultural universes which were always qualified as *national*.

So began a tradition of research based on empirical sources which can still be recognized today, and not only in anthropology but also in other disciplinary traditions interested in the study of national cultures or societies (notably the so-called cultural studies). Yet it is interesting to draw attention to the paradoxical nature of the idea of 'studies of culture at a distance' for, in studying nation-states, researchers were socially and culturally 'closer' than traditional anthropologists in relation to their objects. Thus the fact that traditional methods and practices of anthropology (such as participant observation) were rarely made use of seems to have more to do with the specific properties of the object of study (or with the nature of the relations between researcher and object) than with the supposed impossibility of direct access to it.

National Character Reframed

In the theoretical debates concerning the expression 'national character' we can recognize some of the main questions surrounding contemporary discussions on the status of the nation-state as an object of the social sciences. One finds arguments in favor of the need to renew theoretical models in order to conceptualize empirical objects which need to be thought of as a historical novelty – such as those connected with processes of decolonization, localization, and transnationalization of social and cultural life – or denunciating the supposed limitations behind theoretical models whose origin would be a mere reflection of the world of nation-states which these models were developed to explain in the first place.

The main objections to national character studies can be summed up in three points. First, cultural patterns (obtained through the direct observation of empirical behavior) may become the principles through which one then seeks to explain these very patterns – a vicious circle which appears to be characteristic of culturalism in general (for a critique, see Kuper, 1999). Second, observed behavior in a fraction of the society analyzed would then be abstracted and attributed to all nationals, without a critical enquiry into the social position occupied by that fraction within national society. As such, the idea of national character would serve to disguise a more profound sociological reality; it would become an 'ideology' in the Marxist sense. Finally, in its rush to discuss racist theories, the Culture and Personality school (and, by extension, national character studies) may have shifted from a biological essentialism to a cultural or psychological one, which may then lead it to neglect other dimensions of social life, fundamental to an understanding of national realities and the elaboration of feelings of national belonging – such as institutional aspects related to the presence of the state, or the relations of differentiation, force, and domination between social groups (see Leite, 1969 [1954]).

In an article first published in 1942, Gregory Bateson outlined what remains the most convincing argument in favor of studies of national character. First, he argued that the fact that national characters are constructs does not mean that they do not exist and therefore do not serve to emphasize cultural and social differences. Second, he affirmed that to speak of national character does not imply cultural uniformity, but can, on the contrary, stress the existence of a system of differentiations organized in relation to a pattern (a set of stereotypes) recognized as being dominant. In this sense, national borders (political, cultural, and 'character-based') would serve as a good example of how something which is socially generated can lead to certain effects, acting on the forms of self-perception of the very communities which they differentiate and constitute, ultimately affecting ways of feeling, living styles, and moral configurations (for a similar argument see M. Mauss', 1969 [1921]) classical text; good examples of anthropological studies heading in this direction include Handler (1988) on the objectification of national cultures and Herzfeld (1993) on the social productivity of national stereotypes).

Feelings of national belonging and national forms of organizing social life are, like the Roman god Janus, two-faced. One face is that of the solidarity between nationals, between those who stand united through a relatively homogenous social and cultural base. The other reveals itself at the national borders and the attempts at imposing them and re-enforcing them, through exclusion and nationalist violence. The sociological and anthropological understanding of both faces – as well as of the social force of feelings of national belonging, which are, in effect, the basis for their existence – constitute one of the central themes in contemporary social science. A careful examination of the diverse contents of the discussions brought about by the idea of national character shows us how an advance on this understanding must pass through three theoretical frameworks: we must situate feelings of national belonging alongside other modes of social belonging and identification (ethnic, racial, regional, transnational) as a means of discovering what they may owe to (and reveal about) the universal properties and forms of social life; we cannot ignore the historical and sociogenetical processes behind the formation of categories of identity and the homogenization of forms of being and feeling; and, finally, it is essential to situate the comprehension of national characters as a dimension of the processes which objectify realities (cultures, societies, identities, stereotypes, etc.), both national and international.

Abstract

The concept of 'national character' needs to be used, if at all, with great caution, although its history is of some interest. Discussions of the topic can be traced back at least as far as the writings of Alexis de Tocqueville. The concept was particularly current in the work of anthropologists of the 'culture and personality' school, and in the efforts of other social scientists seeking – during the Second World War and in its aftermath – to understand aspects of the behavior notably of German and Japanese people. Since, it has largely been subsumed into the concept of 'habitus,' and in that sense it has found a place in the writings of Norbert Elias and some of his followers.

The concept of 'national character' is now generally viewed by social scientists with considerable suspicion. It is redolent of the stereotyping of members of a nation, or of a social category, which played a part in some of the great sociopolitical disasters of the twentieth century. More innocuously, notions of national character enter into popular humor: witness jokes of the 'There was an Englishman, a Scotsman and a Welshman …' type, which dates back at least to Shakespeare. Or there are light-hearted but often illuminating popular books such as the Scot A.G. Macdonell's witty observations of the English, or the Hungarian George Mikes's comments on both the English and the Americans, or series like the 'Xenophobes guides' (which are not xenophobic – see for example the *Xenophobe's Guide to the Italians* (Solly, 1995), which is perceptive as well as amusing). But, if used at all by social scientists, the idea of national character needs to be handled with great care and sophistication.

That is not to deny, however, that the concept has a long and – at its best – distinguished history. One can, for example, point to Alexis de Tocqueville's classic work *Democracy in America* (1961[1835–40]), which is a pioneering study of the complex connections between American institutions, culture, and *moeurs*. Moreover, it is a *comparative* study of the *mentalités* of what he conceptualizes perhaps too dichotomously as 'democratic' society in America and 'aristocratic' society in France. Implicitly, indeed, it is a three-way comparison with Britain too, as becomes clear in his other major works, *The Old Regime and the Revolution* (1955), *Recollections* (1970), and *Journeys to England and Ireland* (1958).

The great era for social scientific studies of supposed 'national character' was the Second World War and its aftermath. This was war work for some distinguished social scientists, the aims of whose research included understanding the character and culture of the enemy during the war, and helping to guide the policy of the victorious powers in their occupation of the defeated countries. Thus Ruth Benedict wrote about the Japanese (1946), and Talcott Parsons (1954) about both the Germans and the Japanese. These concerns also lingered on into the early stages of the Cold War.

Shortly after the war, the Canadian social psychologist Otto Klineberg wrote an important survey and critique of the academic literature on 'Personality in relation to nationality' (1950). Dealing first with what he calls 'descriptive accounts' such as Tocqueville's, or such now less well-remembered studies as those by André Siegfried (1927) and Salvador de Madariaga (1928), Klineberg acknowledged that though they often contained interesting suggestions, "they do not carry conviction to the empirically-minded reader … the inference from the facts to the psychological conclusions is not always convincing" (1950: 11). (Of the many selections of Tocqueville's writings, that edited by John Stone and Stephen Mennell – *Alexis de Tocqueville on Democracy, Revolution and Society* (Chicago: University of Chicago Press, 1980) – emphasizes his discovery of several sociological principles that have later been developed more systematically by professional sociologists; but this does not contradict the point made by Klineberg.) They nevertheless contained useful material; for example differences between the accounts of America written by British and French authors might function a little like a projective test, telling as much about aspects of British or French character as about the Americans.

Klineberg took a similar view of the studies written by members of the 'culture and personality' school of anthropology, which include – besides Ruth Benedict's work (1946) on the Japanese – Margaret Mead's comparisons of the Americans (1942), and the Samoans (1927) and Geoffrey Gorer's books on the Americans, the British, and the Russians (1948, 1949, 1955). In particular, Klineberg made the point that such studies in general "give us no indication of the variations among individuals who constitute the national group"; moreover, there are "great differences in the degree and kind of information obtainable about a relatively simple community of 200–300 persons and a complex modern nation" (Klineberg, 1950: 19, 21). The culture and personality school overlapped to a considerable extent with psychoanalytic approaches to the question of national character. Gorer, for instance, paid a good deal of attention to the toilet training of infants (and, in Russia, the practice of swaddling them). Klineberg's criticisms applied to them too; yet he acknowledged valuable insights arising from the careful studies made by Abram Kardiner (1939), who worked in collaboration with a number of anthropologists, from Erich Fromm's study (1942) of how the readiness of Germans to accept Nazism can be understood, and also from the then as yet unpublished work of H.V. Dicks (1972) based on interviews with SS killers.

Turning to vital and social statistics, Klineberg (1950: 25–36) noted their abundance but also the difficulties posed by greatly varying definitions between countries of, for example, mental illness. Even so, he acknowledged that the study of what was a 'typical' mental illness in each country might cast light on its cultures, as might the *absence* of certain known abnormalities. On the other hand, psychiatric interpretations appeared to be of little value (1950: 36–40). As Klineberg observed, there was no evidence at all of the validity of studies of the 'paranoia' supposedly characteristic of German culture: not even the Nazi leaders tried at Nuremberg showed distinctly paranoid characteristics (Kelley, 1947).

Overall, Klineberg observed that there was little consensus among social scientists on the concept of 'national character' or on methods for its investigation, and commented on 'the great complexity' of the problems involved. "A combination of historical study, ethnological analysis, intensive community studies, interviews with a representative sample, and the application of psychological techniques to individuals would seem to be the most promising approach at the present time" (1950: 213, 214).

Whether or not Klineberg's critical survey and noncommittal conclusions had anything to do with it, the concept of 'national character' came to be less and less employed by social scientists in the 1950s and afterward. And yet it does answer to an element in everyone's everyday experience. As Norbert Elias puts it,

> In every country the forms of perception and behaviour, in their full breadth and depth, have a pronounced national tinge. Often one only becomes aware of this in one's dealings with foreigners. In interactions with one's compatriots, *individual* differences usually impinge so strongly on consciousness that the *common* national coloration, what distinguishes them from individuals of other nations, is often overlooked. First of all, one often expects that people everywhere will react to the same situations in the same way as people of one's own nation. When one finds oneself in a situation in which one is compelled to observe that members of different nations often react in a quite different way to what one is accustomed to at home, one mentally attributes this to their 'national character.' As such, it often remains inexplicable. One simply accepts it.
>
> Elias, 2008[1960]: 230, 231

But how is such an everyday notion to be conceptualized for social scientific purposes? If it demonstrated nothing else, Klineberg's survey demonstrated that the problem had not been solved by the mid-twentieth century. One obstacle was the then-prevalent preoccupation of social theorists – notably Talcott Parsons and the numerous scholars whom he influenced in the various social sciences – with drawing rather ridiculous distinctions between personality, social, and cultural systems. Klineberg recognized, but struggled with, the obvious fact that whatever 'national character' might be, it is at once psychological, social, and cultural. The greatest danger, which even he did not entirely avoid, is taking an excessively psychologistic view of national character. That is to say, citizens of a country were often seen as having certain 'personality traits' in common – often in a quasiclinical sense – which were then seen as an independent variable 'causing' cultural and social consequences, such as aggressive militarism and 'tensions affecting international understanding.' In the years after their defeat in the Second World War, the Germans were especially the targets of this kind of approach, as social scientists internationally – and in Germany itself – struggled to understand the rise and fall of the Nazi regime. There was much discussion of what were taken to be the peculiar characteristics of German society, its history, and the psychology of its people. In the most extreme case, a constant 'national character' was traced back as far as Luther (McGovern, 1946). The risk is that 'national character' comes to be treated almost as a prime mover of events, rather than as something that is itself shaped and modified by events, power struggles, and social processes over time. It is better to think about it in terms of *processes* of habitus formation or conscience formation over time. 'Habitus,' a concept that is now especially associated with the work of Pierre Bourdieu but was in fact used earlier by many French and German social scientists, can be understood – as Norbert Elias puts it – simply as 'second nature': it comprises everything that individuals have in fact learned from other people from birth onward but which has become so deeply habituated that it seems even to themselves as something 'natural.' Seeing it in this way makes clear that the attempt to distinguish, even 'analytically,' the levels of personality, social, and cultural characteristics is futile. Many years ago, the anthropologist Clyde Kluckhohn and the psychologist Henry Murray made the point very well:

Every person is in certain respects
1. like *all* other people,
2. like *some* other people, and
3. like *no other* person (1948: 35).

That is to say, there are some characteristics that are common to every human being: every normal person has, for example, the capacity to learn a language. There are usually also ways in which every individual has some distinctive or unique characteristics or quirks of his or her own. But the study of habitus and its formation is concerned with level (2), the level of characteristics that are learned, shared, and transmitted among members of a specific group of people. 'Learned, shared, and transmitted' is one way in which social scientists have defined 'culture,' but habitus is at once cultural, social, and psychological.

It is important to note, however, that processes of habitus formation in this sense are by no means confined to *national* groups and '*national* character.' People may learn, share, and transmit characteristics in any group with a continuing form with which they may identify and be identified – from families to nations and perhaps now to global formations. In complex societies, there are many levels to habitus. It has been hypothesized (Mennell, 1994) that the strongest feeling of identity, and the most general influence on habitus formation, tends to be with what Elias (2010: 182–189, 195–207) called a person's 'survival unit.' By that he meant the largest group within which individuals look for meeting their most important needs – food, shelter, protection, procreation, and orientation. Survival units have tended to become larger in the course of the development of human society, although they can also shrink – for example in times of danger, conflict, and war. In the late-twentieth and early twenty-first centuries, there are have been a number of

instances of supposedly sovereign and unitary nation-states fragmenting into smaller territorial units, often through civil war. Nevertheless, the nation-state has been prominent in the organization of humankind, and the most obvious survival unit with which their members typically identify, at least in the nineteenth and twentieth centuries. That is one reason why, for a time, social scientists tended to focus special attention on *national* habitus.

This strand has most recently been especially prominent in the writings of Norbert Elias. As he remarked in his *magnum opus*, *On the Process of Civilisation*,

> In the conduct of workers in England, for example, one can still see traces of the manners of the landed noblemen and gentry and of merchants within a great trade network, and in France the airs of courtiers and a bourgeoisie brought to power by revolution. In the workers too, we find a stricter regulation of conduct, a type of courtesy more informed by tradition in colonial powers which have for a long period had the function of an upper class within a large network of interdependences.
>
> Elias, 2012[1939]: 426

Elias always stressed the need for *processual* thinking about the intertwining of what he called socio- and psychogenesis. Habitus must be seen as itself the *product* of long-term characteristics of national societies, formed through conflicts and power struggles, both *within* and *between* such societies. In the series of studies published at the end of his life as *Studies on the Germans* (2013), Elias extended this comparison not just to the Germans but also the Dutch:

> The paradoxical situation of having an upper class composed of urban merchants has left deep marks on the habitus of the Dutch. Fostering equality is of prime importance. … In the course of their national development, the Dutch city merchants provided an exemplary case for the solution of the problem of how civilians can protect themselves from violent external attack without being dominated by their own military helpers.
>
> 2013: 15–17

In contrast, the history of Germany produced the opposite result. In the politically fragmented German-speaking lands, the *Bildungsbürgertum* had long aspired to national unification through peaceful means, but after the failure of the revolution of 1848 unification was subsequently achieved by the army on the battlefield – resulting in greater prestige for and deference toward the military caste. Later, Elias emphasized, national defeat in the First World War brought about a profound sense of national humiliation. He made an important connection between political history and events on the one hand and culture and habitus on the other:

> The central question is how the fortunes of a nation over the centuries become sedimented into the habitus of its individual members. Sociologists face a task here that distantly recalls the task that Freud tackled. He attempted to show the connection between the outcome of the conflict-ridden channelling of drives in a person's development and his or her resulting habitus. But there are also analogous connections between a people's long-term fortunes and experiences and their social habitus at any subsequent time. At this layer of the personality structure – let us for the time being call it the 'we-layer' – there are often complex symptoms of disturbance at work which are scarcely less in strength and in capacity to cause suffering than the individual neuroses.
>
> 2013: 24

Others have taken up Elias's ideas on this score. Kuzmics and Axtmann (2007) examined the connections between 'authority, state, and national character' in Austria and England, making especially rich use of literature as a source of sociological evidence. Their book covers the period 1700–1900, and that serves as a reminder that habitus changes: what they depict as characteristic of the English in 1900 now appears almost unrecognizable from the vantage point of the early twenty-first century. "Britain in the recent past," commented Elias (2013: 6) "is a moving example of the difficulties a great power of the first rank has had in adjusting to its sinking to being a second or third-class power." Mennell (2007), writing about the United States, avoided the term 'national character,' and conceptualized the problem as a process of habitus formation. But the strategy was similar: to show the connection between a country's history and the *moeurs* of its people. In particular, Mennell stressed how social and political conflicts internally had over the long term produced a patchy monopolization of the means of violence in the United States; and that, externally, the country's rise to overwhelming power in the world at large had also left its mark on Americans' perceptions of themselves and on their assumptions about and behavior toward non-Americans.

C. Wright Mills (1959: 4) famously defined the sociological imagination as the ability "to grasp history and biography and the relations between the two within society." The strand of thought in sociology, anthropology, and psychology traced in this article stands squarely within Mills's vision. But the important connection between history and biography can generally be explored without using the slightly hazardous concept of 'national character.'

Abstract

National liberation movements (NLMs) constitute diverse socio political movements which share the aim of establishing an independent state for what they consider their nation within the borders of a territory recognized by the international community. These movements prioritize the liberation of their nation over the many other possible social goals, and therefore demand that their people to unite around that priority. NLMs have indeed been among the major political forces which could be found in Europe in the nineteenth century and later, in the twentieth century, expanded to Asia and Africa. The case of African liberation movements are especially considered here. The NLMs can only be understood by reference to the establishment of global capitalism, and despite links to controversies over religion and national identity, economic forces have always dominated such movements.

National liberation movements (NLMs) along with the labor movements have represented major antisystemic forces compelling capital to adjust to the social interests they represented. The expansion of capitalism on a global scale has always generated unequal development and therefore continuously produced NLMs which pursued the target of catching up with the advanced centers of the global system. Such movements expanded in the Americas in response to the mercantilist stage of capitalism, in Central, Eastern, and Southern Europe in the nineteenth century, and in Asia and Africa in the twentieth century. While the circumstances between 1945 and 1980 encouraged such projects, that page of history has now been turned.

NLMs constitute a large spectrum of socio political movements which share in common the target of struggling for establishing an independent state for what they consider their nation within the borders of a territory recognized by the international community. These movements also share that they privilege the struggle for the liberation of their nation over the many other targets of other social movements, and therefore call their people to unite around that priority. The very existence of such movements assumes that the nation either must be united with a view of constituting a single state, or must be separated from a plurinational state in which it is included and that is in their view dominated by another nation, or has to emancipate from a colonial status and achieve political independence of that territory. NLMs have indeed been among the major political forces which operated mainly in Europe in the nineteenth century and later, in the twentieth century, expanded to Asia and Africa. They have shaped major changes in the political geography of the modern world and possibly will continue to do so in some areas.

There are, of course, different approaches to the study of this set of important social phenomena. Some scholars take for granted the preexistence of the nation which these movements mobilize, and therefore focus on the analyses which help in understanding the reasons for their success (or failure), their strategies, tactics, and ability to mobilize objective realities operating within the society or in the field of international politics which may support their project.

Other scholars focus rather on the relationship between the deployment of NLMs and the major changes which singularize the process of modernization of the nineteenth and twentieth centuries. Along with Eric Hobsbawm, Immanuel Wallerstein, and the Austro-marxists, the author will adopt that specific approach for the analysis of the NLMs. Commodification of production, industrialization, urbanization, expansion of education – and all these dimensions of the process of modernization are deeply related to that of capital accumulation – played, in that respect, a decisive role in the crystallization of a new type of community, usually called nation. The new economy and social life implied an intensified use of written communications, and therefore gave to the language used for education and in the workplace a role far greater than it had been the case in premodern societies.

Centers and Peripheries in the Modern World System

Nations as well as social classes are products of modern times, even if one can discover ancestors to them in the past, which anyway have been radically reshaped by the dominant rationale of capital accumulation operating simultaneously at the various local ('national') and global levels. In that respect, the history of capitalism is that of a continuous conflict between the logic of capital accumulation and that through which various other social interests express themselves. NLMs have their place in that historical frame, just as the other social movements, particularly those of the working classes. In fact, these two families of movements – labor and national liberation – have represented, throughout at least the nineteenth and twentieth centuries the major antisystemic forces, compelling capital accumulation to adjust to the social interests that they meant to represent.

National liberation refers to 'nation,' and that term presupposes certain articulations between this reality, real or alleged, and other realities such as the state, the world system of states, the local economy as related to the world economy, and social classes. We owe these concepts and their articulation into a system to the different social theories developed in the light

of the nineteenth century European historical experience. Within this framework, the elaboration of two sets of theories took place – as it turned out, in counterpoint to one another: on the one hand, socialism and the theory of class struggle; on the other hand, nationalism and the theory of class integration into the nation-state. Both theories take account of many aspects of the immediate reality which is marked both by social struggles ending in deep transformations of capitalism and even in revolutions, and by struggles between nation-states ending sometimes in war as well as NLMs ending in many cases in the creation of new independent states. For protagonists of these theories, they have proven to be potent guides to action.

The expansion of capitalism on a world scale has always been, and continues to be, based on unequal economic and, therefore also, political relations between those areas which constituted themselves as full-fledged centers of the system controlling the global process of accumulation, and those areas which have been submitted to the logic of that accumulation, i.e., the peripheries. Therefore, the relationship between state and nation on one the hand and the economic system on the other is not similar in the centers and in the peripheries of global modern capitalism. In the centers there is a rough coincidence between the state (whether national or multinational) and an autocentric productive system; in the peripheries such a coincidence is always lacking. That coincidence between the state, the nation, the high level of capitalist transformation, and the dominant position of such states in the world capitalist system which led these central partners to form 'autocentered' interdependent economic units enjoying a high degree of autonomy vis-à-vis each other, defines a possible field for 'national' economic policy. The instruments of this policy – the national centralized monetary system, customs, the network of material infrastructures in transport and communications, the unifying effects of a 'national' language, the unified administrative system, and so on – enjoy a definite autonomy in relation to the constraints imposed by an economy operating worldwide. Relations between classes, however wrought, are relegated to and by the national state.

True, there is no Wall of China to separate these national systems from the world system that they constitute. Internal social relationships are partly dependent upon positions occupied by the national states, in the world hierarchy. If social relations permit it, these states can improve their position by pursuing coherent national policies. This effectiveness in turn facilitates social compromise and, without 'abolishing the class struggle,' puts definite limits to conflicts.

However, at closer inspection it appears that these circumstances, pervasive but limited in time to the nineteenth century, are even more limited in space. Around a few 'model' nation-states, the world of the capitalist system – structured by different pasts which in turn lost their legitimacy and efficacy – remains undefined in the light of an uncertain and obscure future. Therefore, the problem changes when we quit the limited framework imposed by the central bourgeois nation-states. For this forces us to examine more closely 'regions' whether they are organized into the states or not. Regions are peripheral in relation to continuously expanding capitalist reproduction. On this level there is only a central state, i.e., a state which masters external relations and submits them to the logic of autocentered accumulation. On different levels, there are only 'countries,' which are administered from outside as colonies or semicolonies; these appear to be independent but are incapable not only of molding the outside according to their needs, but also of avoiding their drift and shaping from outside.

The consequence of that fundamental and continuous contrast between centers and peripheries immanent to the history of really existing global capitalist expansion is that 'national liberation movements' have been continuously produced by the uneven development associated with that expansion. These movements have always pursued the same major target, that of 'catching up' with the advanced centers, through constructing in their turn a modernized independent autocentered nation-state able to act as an autonomous participant in the global capitalist system. They always have nurtured a basic ideology of modernization and national building. In their struggle against the dominant forces in the global system, NLMs have also often attempted to build 'international common fronts' associating the movements involved. Mutual sympathy and common strategic and tactic approaches helped in constructing such common fronts. These common fronts often survived the victory of the NLMs, i.e., after those movements had conquered political independence. Yet these fronts were also gradually eroded by the very success of the NLMs. The new states pursued their own policy targets within the global system, which led to their insisting on their particular interests and specific strategic and tactical policies aiming at helping them to achieve them. The similarity with the other major antisystemic movement – that of the working classes and socialism which have built their own successive 'internationals' – is striking.

Stages of Deployment of the NLMs

Capitalist global expansion has moved through successive stages. For each of those stages specific forms of the relationship between centers and peripheries can be identified. The NLMs produced in each stage have therefore been confronted with specific challenges.

During the mercantilist stage of capitalist expansion (1500–1800) the American continent was conquered and indigenous populations subjugated when not exterminated, Africans were imported as slaves, while migrants from Europe either created autonomous small production systems (in New England, for instance) or constituted themselves as the local ruling class operating as a transmission belt for the metropoles, dominant powers (slave owners and masters of encomiendas). The NLMs in the late eighteenth century (the 'American revolution') and in the early 1800s (in Latin America) were led by those local ruling classes of European origin, disregarding the interests of subjugated peoples (black slaves and indigenous Indians). Haiti is in this respect an exception. The common front which was constituted with a view to excluding European powers from the continent was quickly captured by the new capitalist center which emerged in the USA (that is the meaning of the Monroe declaration in 1823). The pattern of an uneven relation was gradually constructed in that frame between the US center and its Latin American periphery. It was only much later,

in the twentieth century, that nationalist bourgeois movements started questioning that uneven relation, along in some cases with a revival of indigenous Indian peoples movements. The Neozapatistas (Chiapas) movement in Mexico is the most recent expression of that unfinished struggle for national liberation and social progressive change.

A second wave of NLMs developed throughout the nineteenth century in Central, Eastern, and Southern Europe, associated with the expansion of capitalism beyond its northwestern European corner of origin. In two cases, Germany and Italy, these movements led to the constitution of new nations, which became new capitalist centers. Further to the east the three multiethnic autocratic empires (the Russian, the Austro-Hungarian, and the Ottoman) were assaulted by the expansion of capitalism, moved by a conjunction of internal forces (produced by industrialization and the formation of modern social classes – a bourgeoisie and a working class) and the impact of external forces dominating the global system. The dilemma with which those societies were confronted was the following: could capitalist development flourish within the frame of such large states, becoming multinational and democratic, or should they be dismantled on a more or less national base? In these countries more than elsewhere the various class struggles (between the autocratic leading groups of the old regime and the new bourgeoisie, between the latter and the working class, between the large landowners – often of different ethnic origin – and their peasants), the political struggles (for democracy, for socialism), and the 'national question' overlapped and interacted in a complex manner. The major organizations within the socialist movement were rather in favor of maintaining the large multinational state (so was the meaning of the struggle of the Austro-marxists for cultural autonomy). However, the peasant and bourgeois movements favored 'national liberation first,' and that option was finally the one which succeeded in imposing itself.

Simultaneously, during the second half of the nineteenth century, there was an extraordinary expansion of global capitalism which conquered Asia and Africa and colonial (or at least semicolonial) systems were established there in most cases. The national question was moving out of Europe and NLMs of a new type started being constituted, inspired by the local elites and fractions, at least of the new bourgeoisies. The ancestors of those NLMs which played a decisive role in the making of the twentieth century could be identified at least, in China, India, Persia, Egypt, and Syria, where it animated cultural revivals (such as the Arab Nahda) and the first political modern organizations. These new NLMs related to class issues in a variety of ways, but in general they gradually became what has been labeled later as 'antifeudal–anti-compradore' political movements, associating in their struggles for reconquerring the lost national independence and modernization of the 'external enemy' ('imperialism') and its local allies (precisely the 'feudals' and 'compradores'). Yet the dominant force among the international socialist movement – the social democracy of the Second International – ignored those new NLMs, overlooked their importance for the future and shared the dominant European imperialist ideology of the 'civilization mission' of colonialism.

The colonization of Asia and Africa has nationally produced a wave of most important NLMs which finally won their struggle for national independence after World War II and played an important role in the changing of the face of the world since. The NLMs of Africa and Asia were very different in outlook. The past and recent history of their peoples, the social forces, the political and ideological parties and trends which they represented, their visions of the future of the societies to be constructed or to be reconstructed, and its relationships with the West were all subjects on which they differed. However, what brought them together was their common project, which included the completion of the political decolonization of Asia and Africa. Beyond the Afro-Asian States which emerged out of the victories of NLMs after World War II all considered that the political independence they had regained was only the means, the end being the achievement of economic, social, and political liberation. In the opinion of by far the majority 'development' would be possible through interdependence within the world economy. The NLMs and then after the new states they created never intended to 'leave the system,' or 'delink' even if they did not all share the same strategic and tactical vision of 'development.' But, to varying degrees, they considered that the building of an independent, developed economy and society (even within global interdependence) implied a certain amount of 'conflict' with the West in its dominance (the radical wing thought it necessary to put an end to the control of national economies by the capital of foreign monopolies). Moreover, anxious to safeguard the independence which they had regained, they refused to take part in the military struggle at planet level, and to serve as bases for the surrounding of the socialist countries which American hegemony was attempting to impose. However, they also thought that if they refused to be part of the Atlantic military alliance, this did not imply that it would be necessary for them to seek the protection of the latter's adversary, namely the USSR, whence 'neutralism' and 'non-alignment.'

Wilson's 'principle of nationalities' (a state for each nation), which was restricted to Europe after World War I, was thereafter partly recognized to Asian and African peoples by the UN after World War II. Yet it took several more decades for the NLMs to achieve their target. That success was favored to a certain extent by the bipolarity which characterized the international system in those times.

The coming together of the Afro-Asian states had already begun by the setting up of the Arab–Asian group within the United Nations in the late 1940s with a view to defending the independence of the colonies in arms. In 1955, the foremost Heads of State of the countries in Asia and Africa which had regained their political independence met for the first time at Bandung. Nasser, Nehru, Sukarno, and Chou En Lai were to have a considerable influence on their times, even although the experience of the new powers they represented, and to a large extent inspired, was very recent. India and Indonesia had been independent for barely 10 years, communist China for not quite 5, and in Egypt the monarchy had disappeared from the scene only 3 years previously. The struggle for the achievement of the historical task of independence was not over: the first war in Vietnam was barely over when the second one loomed on the horizon, the Korean war had just ended in a status quo, the Algerian war was at its height, the decolonization of Africa south of the Sahara had not even been contemplated, the Palestinian drama was still in its first stages, South Africa was

closing itself in hard apartheid. Bandung had the effect of reinforcing this rapprochement and of giving an impetus to this struggle. Three years later, in independent Accra, Kwame Nkrumah declared that 'Africa must unite.' But it was only to do so once independence had been achieved and after the failure of Nkrumah's pan-Africanism, followed by the demonstration of the impotence of the two groups formed as a result of the Congo crisis (the Casablanca group and the Monrovia group between 1960 and 1963), in the minimal form of the setting up of the OAU in 1963.

From summit to summit, throughout the 1960s and 1970s, 'nonalignment' was nevertheless gradually to change direction from a position of a front of political solidarity based on the support for NLMs and struggles and the refusal of military pacts, to a position of building a common front with a view to reinforcing collective economic demands from the North. It inspired the 'decades of development' in the United Nations system, the creation of UNCTAD in 1965, and a whole series of global negotiations on crucial economic global issues. The struggle for a 'new international economic order' which began in 1975 after the October 1973 war and the revision of oil prices was the culmination of this development and the beginning of its end.

The West had no intentions of accepting the spirit of Bandung as a foregone conclusion on either the political level or on that of the economic struggle. The project of society which constituted a kind of basic charter for the NLMs and thereafter inspired the policies of the Asian and African states did exist, although it was often implicit and imprecise. This project, setting aside its various concrete manifestations and the specificities of its expression at national level, can be defined in terms of the following elements: (1) the desire to develop the forces of production and to diversify production (in particular to industrialize); (2) the desire to ensure that the nation-state controls and directs the process; (3) the belief that 'technical' models constitute 'neutral' data which, once mastered, only have to be reproduced; (4) the belief that the initiative did not imply its being initiated by the people in the first instance but only their support for state actions; and (5) the belief that the process is not fundamentally in contradiction with the participation in exchange within the world capitalist system, even if it implied conflicts at times with the latter.

The circumstances of capitalist expansion between 1955 and 1970 to some extent encouraged the crystallization of this project. The implementation of this national bourgeois project implies that the hegemonic national, bourgeois class, by means of its state, controls a series of processes which include as a minimum:

1. the management of the reproduction of the labor force, which implies relatively full and balanced development so that local agriculture, for example, is capable of providing the elements required for this reproduction in sufficient quantity and at suitable prices to ensure the valorization of capital;
2. the control of national natural resources;
3. the control of local markets and the capacity of entering the world market on competitive conditions;
4. the control of the financial circuits enabling the centralization of surpluses and the directing of its productive usages;
5. the control of the technologies being used at the level of the forces of production concerned.

Seen from this angle, the experiences of the Third World inspired by the ideology of NLMs can be divided into two categories: that of the countries which have attempted nothing more than the acceleration of growth without considering the implementation of the conditions outlined above (Ivory Coast, Kenya, Pakistan, Saudi Arabia, etc.) and that of the countries which have attempted to implement the conditions outlined (Nasser's Egypt, Algeria, Tanzania, India, Brazil, South Korea, etc.). It is obvious that the classification does not necessarily distinguish between regimes concerned with the implementation of a modicum of social justice and reforms, in particular agrarian reforms (e.g., Nasser's Egypt and South Korea) and those which have had no hesitation in accepting the intensification of social inequality (e.g., Brazil). Nor does it necessarily distinguish between the attitudes toward transnational capital (Brazil and Kenya both encourage the latter, but the former attempts to integrate it into its own national policy, whereas the latter simply adjusts to its demands), nor even between the question of the political relationship of conflict or alliance with the East and the West. It is true that there are correlations but the variations in composition as a function of the concrete situation make a special case of each of the Third World countries. However, over and above the variety of experiences, the fact remains that the most coherent implementations have taken place when there has been the conjunction of an intense nationalist struggle and a powerful social revolution. Led by communist parties, these NLMs in China, Vietnam, and Cuba are the most distinct examples of such a radicalization.

It is no longer possible to disregard the inadequacies of all these attempts which collapsed when circumstances became favorable to their overthrow or erosion. The food and agricultural crisis, the external financial debt, the increased technological crisis, the external financial debt, the increased technological dependence, the fragility of the capacity to resist possible military aggressions, and the advance of waste on the lines of the capitalist consumption models and of their ideological and cultural content point to the historical limits of the attempts. Even before the present crisis presented the possibility of an 'offensive from the West' which would succeed in reversing the trends, these inadequacies had already led to an impasse.

In this sense, we may consider that the NLM project under consideration deserves to be described as a national, bourgeois project. The project for the society that the NLMs had in mind was, as we have shown above, that of creating a new state integrated in the global capitalist system. In that perspective the ruling class imagined itself becoming similar to that which controls the process of accumulation in the capitalist centers, and therefore it deserves to be qualified as 'bourgeoisie' (including state bourgeoisie forms), although of course it constituted itself out of different historical origins. Moreover, it has proved to be impossible. In this sense, history has proved that the national bourgeoisie is incapable, in our times, of implementing what it achieved elsewhere, in Europe, in North America, and in Japan in the nineteenth century. A concrete examination of the history of NLM ideologies and the policies they inspired in the Third

World independent countries would illustrate that fact: that of the uninterrupted sequence of attempts by the national bourgeoisie, of their repeated failures and of the submission to the demands of subordination which followed on each occasion; in Latin America since the nineteenth century (we shall only refer here to the more recent examples of the Mexican revolution between 1910 and 1920 and of Peronism in Argentina), in India (e.g., the change in direction since Nehru's 'first plan' until the return to power of the right after the first failure of the Congress), as in numerous Arab and African countries.

The favorable economic circumstances at the end of World War II were indeed exceptional and could not last. On the economic level, strong growth in the 'North' facilitated 'adjustment' in the South. On the political level, peaceful coexistence along with the rise of Soviet power, and its combination with the decline of the old French and British colonialisms and the rise of the Afro-Asian struggles for independence made the Soviet alliance truly efficient.

New Challenges, Problems, and Perspectives

The page of that history of NLMs has now been turned and the global capitalist system has entered in a new stage of its expansion. In this respect it is often said that any attempt at a national development has become irrational and impossible, that the challenges are basically global and therefore cannot find their solutions; but at that level, in other words that there is no more national capital, national bourgeoisies, but only a globalized capital managed by a globalized bourgeoisie. Yet the system is not moving toward reducing global polarization, but is rather deepening it. Uneven development between centers and peripheries and therefore nations and peoples not only continues but aggravates, albeit in new conditions. The global capital and bourgeoisie – if existing – would be restricted to the central triad, whereas in the peripheries they are bound to be compradore transmission belts of domination of the first. Therefore, the national question remains on the agenda; it continues to be a real challenge. What can be said in that respect is that the change marks the end of an epoch which in the case of Asia, Africa, and Latin America can be called the century of the national bourgeoisie, in the sense that it has precisively been marked by successive national bourgeoisie edification attempts. The Third World bourgeoisie now finally sees its own development in terms of the compradore subordination imposed upon it by the expansion of transnational capitalism. A new wave of NLMs should therefore be expected, different in their social targets and methods from the previous ones. The crystallization of the alternative new national popular (not bourgeois) strategy involves a merging of three conditions. First, delinking in the sense of a strict submission of external relations in all areas to the logic of internal choices taken without consideration of criteria relating to world capitalist rationality. Second, a political capacity to operate social progressive reforms through advances of democracy. This political capacity is a condition of delinking – since existing hegemonic classes have no interest in it. Delinking without that transfer of political hegemony has little chance of emerging, and if it did emerge under such conditions, it would lead to an impasse. Third, a capacity for technological absorption and invention, without which the autonomy of decision making acquired could not be realized.

Thus defined, the conditions for a positive response to the challenge of history appear severe, and any merging of such conditions remote. That is not surprising. The response to new challenges never comes spontaneously. It takes time for the social structures to stabilize, for the new forms of social movements to produce efficient strategies, for them to formulate legitimate ideologies in keeping with the real challenges. In the meantime, what we have is rather chaos, and therefore disarray and nostalgias of the past, in other words, false responses to real problems. It is in this frame that we can observe revivals of movements which label themselves 'national liberation,' usually on the basis of ethnicity and religion, denying importance to any other dimension of social reality, such as class. Often presented by the dominant ambiguous ideologies as 'primordial' in the sense of being the expression of a transhistorical fundamental 'difference' and 'specificity,' these movements are in fact more of the nature of being a symptom of the crisis rather than an answer to it.

Abstract

Domestic extremists, such as Al Qaeda and associated movements, far-right extremists, and far-left extremists, currently pose a threat to national security. These threats are dynamic and national security policies need to be sensitive to the overall criminal offending patterns of specific movements, characteristics of the specific movement and its supporters, and the unintended consequences of counterterrorism policies. This article provides an overview of the most active domestic extremist movements, reviews current national security policies, and provides suggestion to reduce the risks posed by domestic extremists.

This article provides an overview of the most active domestic extremist movements, reviews current national security policies, and provides suggestion to reduce the risks posed by domestic extremists. The FBI defines domestic terrorism as "domestic acts of violence in furtherance of political, religious, racial or social ideology" (Mueller, 2012). Thus, the perpetrator(s), victim(s), and incident must occur within one country for the act to be deemed domestic terrorism (Parkin et al., 2011). According to Hewitt (2003), more than 3000 terrorist incidents, that took more than 700 lives, were committed in the United States between 1954 and 2000. Most of these incidents were perpetrated by domestic extremists. In fact, LaFree et al. (2006) found that each year usually about 85% of terrorist attacks are domestic. In addition, Freilich and Chermak (2012) found that since 1990, domestic extremists committed more than 650 financial schemes, such as tax avoidance, money laundering, and material support, which resulted in more than $700 million in financial losses.

Smith (1994) reviewed federal prosecutions of terrorists between 1980 and 1989 and subdivided domestic terrorism into Puerto Rican, Jewish, Left wing, Right wing, and special interest or single-issue terrorism. At that time, law enforcement considered antiabortionists – termed 'single-issue terrorists' by Smith (1994) – and right-wing groups the greatest threat to national security (Carlson, 1995; Freilich et al., 2009b; Riley and Hoffman, 1995). Currently, right-wing and single-issue terrorism such as eco/animal rights extremists continue to pose a threat, but Puerto Rican and Jewish terrorism have waned (Parkin et al., 2011). Not surprisingly, Al Qaeda and associated movements (AQAM) is considered by many to be the single largest threat to national security. Freilich et al. (2009b) survey of state police agencies, found that Islamic extremists were ranked as the greatest threat to state and national security, but other domestic groups were also of grave concern. The US Extremist Crime Database (ECDB), which uses open source documents to track violent and financial crimes perpetrated by domestic extremists, found that AQAM supporters have caused the most fatalities (over 3000) since1990. Interestingly though, far-right perpetrators committed more ideologically motivated homicide attacks (150+) than the 30 events committed by AQAM supporters (Freilich et al., 2012).

Domestic extremists' threat to national security expands beyond the potential loss of lives and property damage from acts of terrorism. Since 1990 far-rightists have committed thousands of violent and nonviolent crimes (Freilich et al., 2009b). Domestic extremists engage in a range of preparatory and nonideological or 'routine' crimes (Chermak et al., 2010; Freilich et al., 2014b). Terrorist organizations require funds to finance terror attacks and to cover operational costs, such as living expenses for members who live on the compound, security, pamphlets, and other propaganda materials and recruitment (Chermak et al., 2011). Although some funding is obtained via legitimate business ventures and donations from supporters, terrorist organizations must often resort to illegitimate activities, such as drug smuggling, fraud, forgery, counterfeited goods, and money laundering (Chermak et al., 2011).

This article first describes the range of terrorist and criminal behavior typical of three types of domestic extremist groups: AQAM, far-right, and eco/animal rights extremists. Detailed descriptions of these ideologies may be found in Freilich et al. (2014b) and are available upon request. Next, we discuss current national security policies. The article concludes with policy recommendations that consider the overall criminal trajectory of domestic extremists and their relative risks to national security.

The Scope of the Problem

This section provides a general overview of the types of domestic extremists that currently pose a threat to national security. A brief description of the types of terrorist and criminal behavior commonly committed by each movement is provided. This section provides a framework to situate the discussion of current counterterrorism (CT) policy and their limitations.

Al Qaeda and Associated Movements

Supporters of AQAM include extremists affiliated with groups such as Al Qaeda, Al Fuqra, al-Gamaa al-Islamiya, Pakistani

Taliban, Hamas, and Al Shabaab (Freilich et al., 2012). The Center on Law and Security (2011), based at the New York University School of Law, investigates AQAM cases that are classified as terrorism-related cases by the federal government. The Center on Law and Security identified 578 federal AQAM cases since 11 September 2001 to 11 September 2011. Most of these defendants ($n = 241$) were American citizens. Frequent charges included terrorism, national security, fraud and false statements, immigration violent crimes, weapons possessions, racketeering, and theft and fraud (Center on Law and Security, 2011).

The ECDB has identified 30 acts of ideologically motivated homicide incidents (i.e., the perpetrator killed others), committed by supporters of AQAM since 1995, which claimed over 3000 victims (Freilich et al., 2012). Almost half of these incidents (48%) were committed by lone actors. Since 1990, supporters of AQAM have also committed 12 attempted homicide incidents and were involved in 66 foiled violent plots, which were prevented by law enforcement. About 17% of AQAM supporters who committed an act of homicide also had a history of prior arrests. The homicide incidents ($N = 30$), attempted homicide incidents ($N = 12$), and violent failed or foiled plots ($N = 66$) were committed by 210 individuals, as some incidents involved multiple perpetrators.

Although the period for researching the ECDB by Freilich et al. (2012) was longer (1990–2012 vs 2001–11) than that covered by the Center on Law and Security (2011), the latter identified more perpetrators than the ECDB (578 vs 446). This could be because some of the cases identified in by the Center on Law and Security would not meet the ECDB inclusion criteria (See Freilich et al., 2012 for a detailed description of the ECDB inclusion criteria). Also, since the Center on Law and Security analyses federal terrorism-related cases, they would have excluded financial and routine crimes prosecuted in state courts. However, many AQAM cases appear in both the ECDB and the Center on Law and Security databases.

The ECDB, in addition to the violent acts described above, has also identified an additional 127 financial or material support schemes committed by at least one AQAM supporter since 1990. The ECDB defines a financial scheme as an "illicit financial operation involving a set of activities [i.e., techniques] carried out by one or more perpetrators to obtain unlawful gain or other economic advantage through the use of deliberate deception" (Belli, 2011: p. 64). Significantly, 25% of these schemes were linked to violence. These financial and material support schemes were committed by over 446 perpetrators. Importantly, these schemes were often carried out with nonextremist collaborators and utilized the national and international banking system, that is, wire transfers, cash deposits, and checks (Freilich et al., 2013). Many of these schemes were preparatory crimes, i.e., perpetrated to raise funds for 'jihad' in the US or abroad. This highlights the need to track the criminal behavior of extremists, in addition to their terrorist behaviors.

Extremist, in fact, require funds for their terrorist activities and organizational expenses. Since 2007, the frequency of federal material support charges has been increasing, as compared to other terrorism charges. Material support charges encompass monetary, weapons, or service support provided by others or the perpetrator. In 2007, material support charges accounted for 10% of all federal AQAM cases, but this figure rose close to 90% in 2011 (Center on Law and Security, 2011). This suggests either a change in prosecutorial strategy (attempting to reduce terrorism but cutting off the source of funding for the attacks) or an increase in support or sympathy for AQAM among domestic extremist. This backlash effect is discussed in greater detail in the section on CT and countering violent extremism (CVE) below.

Far-Right

Members of the American far-right movement, who believe in conspiracy theories, are extremely distrustful of federal authority and officials, and fiercely protective of their personal liberties, such as the right to own guns (Freilich et al., 2014b). Since the far-right does not recognize the authority of the federal government, they consider many federal laws and regulations, such as taxes and vehicular licenses to be invalid. Racist, anti-Semitic, and homophobic beliefs are also prevalent among some far-rightists (Freilich et al., 2014b).

The ideology of the far-right may lead some members to engage in (1) acts of terrorism to inspire political, social, or religious change, or (2) criminal acts as a result of their extreme beliefs (Chermak et al., 2010). For example, far-rightists' racists, anti-Semitic, and homophobic beliefs may motivate members of the movement to commit hate crimes, while their antigovernment sentiments could motivate far-rightists to engage in tax avoidance schemes, react negatively or violently to routine law enforcement activities (e.g., a vehicular stop) or actively target government agencies and officials.

According to Hewitt (2003), between 1978 and 2000, more than 250 persons were killed from terrorist attacks by far-rightists. More recently, analysis of ECDB data found that since 1990 far-rightists have been responsible for the loss of over 600 lives, including victims of the Oklahoma City bombing (Freilich et al., 2014b). These lives were claimed in over violent 370 incidents, which includes acts of terrorism, hate crimes, attacks against abortion providers, inter- and intragroup conflicts, and nonideological motivated homicides (Freilich et al., 2014b). Importantly, over 150 of these homicide incidents, that took around 400 lives, were ideologically motivated. Many of the ideologically motivated homicides (35%) were committed by lone actors (Gruenewald et al., 2013). Close to 62% of lone wolf far-rightists and about 50% of nonloner far-rightists who committed a homicide had a history of prior arrest. Not all crimes perpetrated by the far-rightists are motivated by their extreme beliefs. About 20% were nonideological but linked to the movement (e.g., inter- and intragroup conflicts) and approximately 40% were motivated by personal reasons not linked to the movement (Freilich et al., 2014a,b).

Far-rightists also engage in nonviolent crimes. Since 1990, far-rightists have committed more than 540 financial schemes (Freilich et al., 2014b). Unlike the AQAM, far-rightists typically engage in tax-related financial schemes, such as filing false tax returns, refusing to file tax returns, filing false liens, making frivolous tax claims, or creating elaborate offshore tax shelters to hide income from the IRS (Belli, 2011). Although some far-rightists were motivated by greed or a combination of greed and ideology, many far-rightists

were motivated by their extreme antigovernment beliefs (Belli, 2011).

Although many criminal acts committed by far-rightists are committed by individuals who belong on a far-rightist group, there is evidence to suggest that criminal acts by loners or "self-radicalized extremists…with no ties to extremist organizations" (Gruenewald et al., 2013: footnote 1) have been increasing. Gruenewald et al. (2013) argued that since leaders of the far-right movement, such as Louis Beam, Alex Curtis and Tom Metzger, began to promote the concept of 'leaderless resistance' as a strategy to avoid detection by law enforcement, loner attacks might be increasing in prevalence, as evidenced by the decreased number of individuals per case indicted for federal terrorism offenses (see also Damphousse and Smith, 2004). Gruenewald and colleagues used data from the ECDB to compare loner attacks ($n = 47$) to homicides committed by multiple perpetrators ($n = 92$) during 1990–2010. They found that since 9/11, loner attacks were significantly more likely to occur than homicide events committed by nonloners. Loners tended to be older (mean = 35.3) than other far-right homicide perpetrators (mean = 27.2), and more socially isolated. Finally, Gruenewald et al. (2013) found that loners were significantly more likely than other far-right homicide perpetrators to suffer from a mental illness (40% vs 8%).

Environmental and Animal Rights Extremists

Environmental and animal rights extremists also pose an important national security threat (Carson et al., 2012; Freilich et al., 2011; Smith, 1994). A 2008 Department of Homeland Security report named ecoterrorists as the largest terrorist threat to national security. Similarly, the survey of state police agencies ranked environmental extremists as the second largest national threat and animal rights extremists as the third largest national threat (Freilich et al., 2009b). Animal and environmental rights extremists typically believe in biocentrism, which states that everything in nature has inherent value and humans do not hold a superior position in the ecosystem. They also believe that the ecosystem is in imminent danger; the government and corporations are responsible for this danger; and there is a dire need to protect the ecosystem (Carson et al., 2012; Freilich et al., 2011).

Carson et al. (2012: p. 297) also noted that animal and environmental rights activists subscribe to the philosophy of 'peaceful coexistence with nature' – and unlike extremists – generally prefer legal avenues to accomplish their goals. However, some animal and environmental rights extremists perpetrate acts of terrorism and crimes in their attempts to ensure biodiversity. Environmental rights extremist groups, such as the Earth Liberation front (ELF) and The Family are concerned with protecting the entire ecosystem, while animal rights extremist group such as the Animal Liberation front (ALF), are more narrowly focused on ensuring equality of animals (Carson et al., 2012).

Environmental and animal rights extremists engage in acts of property damage (e.g., arson, theft, vandalism, monkey wrenching/sabotage, tree spiking, and releasing animals held in captivity) against organizations and individuals they believe to be harming the environment and/or animals, but rarely target individuals. Thus, some researchers (e.g., Carson et al., 2012; Smith and Damphousse, 2009; Vanderheiden, 2005) are reluctant to use the term 'ecoterrorists' or 'ecoterrorism.' Instead the preferred terms are 'radical ecogroups' to refer to the movement and 'ecotage' – sabotage of property believed to be involved in destruction of the ecosystem or animal life – to describe the criminal activities of the movement. Carson et al. (2012) examined illegal activities from 1970 to 2007 that were motivated to protest abuse or destruction of the environment and/or animals. The authors identified 1069 criminal acts committed by environmental and animal rights extremists. Only 17% of these incidents were classified as acts of terrorism. Although Carson et al. (2012) noted the possibility of nonidentification of incidents that occurred in the 1970s, they argued that federal law enforcement had overestimated the risk posed by radical ecogroups, since only one incident in their database resulted in death. The ECDB has uncovered several additional violent plots not identified by Carson et al. (2012), however, this project is ongoing and results are not yet available (Freilich et al., 2014b).

According to Jarboe (2002, see also Freilich et al., 2011), between 1996 and 2002, environmental and animal rights extremists committed more than 600 criminal acts and have caused more than $40 million in damage. Jarboe's (2002) findings are consistent with a 2008 DHS report noted that ecoterrorists had committed more acts of terrorism in the US than any other group and caused more than $100 million in damages in the 25 years from 1981 to 2005 (DHS, 2008; see also Carson et al., 2012).

Animal and environmental rights extremists tend to be younger, have higher levels of education, and have better jobs than far-right extremists (Smith, 1994). Carson et al. (2012) noted that these individuals tended to be guided by a respect for life (though not for property) and an awareness of the legal consequences of their actions. Many of the extremists interviewed by Carson et al. (2012) mentioned a preference for legitimate advocacy activities and unwillingness to face legal sanctions for illegitimate behavior.

According to Carson et al. (2012), environmental and animal rights extremists generally operate using small cell structures or leaderless resistance, which makes it more difficult for law enforcement to arrest and convict members of radical ecogroups. However, state police officials surveyed by Chermak et al. (2010) did not believe that supporters of ELF/ALF normally commit crimes in small cells or alone. Perhaps this was due to unidentified cases in Carson's et al. (2012) study or law enforcement officials might be unaware of the offending patterns of extremists (Chermak et al., 2010). The aforementioned moral, educational, and demographic characteristics, as well as the typical group structure of radical ecogroups, have implications for desistance policies, which will be discussed in the next section.

Current Domestic Terrorism and Extremism Policies

Initial CT efforts after 9/11 focused primarily on supporters of AQAM, as is common after a focusing event. Since 2011, DHS has attempted to implement evidenced-based practices. Their current policies are based on over 75 assessments

on homegrown extremism, and extends beyond Al Qaeda-influenced individuals and groups (DHS, 2012). Current policies by national, state, and local authorities to address the national security threat of domestic extremists include: new legislation and more stringent penalties; the use of confidential informants to infiltrate terrorist groups (Center on Law and Security, 2011); CT training and CVE programs (DHS, 2012).

New Legislation and Stricter Penalties

Lum et al. (2006) found that increasing legal punishments and efforts to crack down on terrorism have almost no effect or cause a displacement effect as extremists find more vulnerable targets. Excessive compliance measures, especially those that violate civil rights and liberties, have been criticized for having a backlash effect and increasing support for AQAM (Lum et al., 2006). The overt use of this strategy against domestic supporters of AQAM declined several years after 9/11, and attempts have been made to integrate outreach programs in immigrant communities, to reduce perceptions of exclusion and the risk of radicalization (DHS, 2012). This strategy is discussed in greater detail in the upcoming section, CT Training and CVE Programs.

Excessive compliance measures can also have a backlash effect among far-rightists (Freilich et al., 2014a). Sprinzak (1995) and Kaplan (1995) argued that such excessive compliance measures would result in an 'us vs them' outlook by both law enforcement and far-rightists. This mind-set could increase the level of radicalization among far-rightists and, subsequently, the likelihood of attacks made against government officials and law enforcement (Kaplan, 1995; LaFree et al., 2009; Pridemore and Freilich, 2007; Sprinzak, 1995). Support for these claims were found by Gruenewald et al. (2013), which found that more than 50% of loners and other far-rightists who committed acts of homicide from 1990 to 2012 had at least one prior arrest. According to Gruenewald et al. (2013), many of these arrests were for nonviolent crimes. Thus, far-rightists' offending behavior progressed from nonviolent to violent crimes (Gruenewald et al., 2013). Far-rightists' offending also escalated from nonideological to ideological crimes (Freilich et al., 2014b), which further supports the thesis that excessive compliance measures increases radicalization.

Nevertheless, the arrest history of far-rightists provides opportunities for law enforcement to identify extremists before they commit a violent crime or terrorist attack. Chermak et al. (2010) recommend that law terrorism task forces be expanded to include state tax agencies, the IRS, Treasury Department, and state-land use and zoning agencies. Chermak et al. (2009a) caution, though, that penalties, which disrupt the funding sources of extremist groups, could have a backlash effect, as they find alternative, illicit sources of revenue.

However, a backlash effect is not anticipated among environmental and animal rights extremists. In fact, Carson et al. (2012) recommend increasing the penalties for ecotage committed by environmental and animal rights extremists. The authors argued that stricter penalties would not create a backlash effect and instead would reduce likelihood that environmental and animal rights extremists would engage in ecotage (Carson et al., 2012). These extremists tend to be younger, better educated, and have higher status jobs than far-rightists (Freilich et al., 2011). Thus, they risk a greater future economic loss than the typical far-rightist. Members of radical ecogroups interviewed by Carson et al. (2012) were very aware of the legal penalties and repercussion of their actions and expressed a desire to avoid such penalties. An increase in penalties for ecotage would change the cost–benefit assessment and discourage animal/environmental rights extremists from engaging in ideologically motivated offenses, especially if this tactic is combined with the provision of legal avenues to political, social, and economic change (Carson et al., 2012).

The risk of a backlash effect would also be less likely with nonextremist collaborators. As noted by Freilich et al. (2013), many supporters of AQAM and the far-right commit financial crimes to fund their organizations and future violent attacks. These financial schemes are normally accomplished with the aid of professional services provided by nonextremist accomplishes. Since these collaborators are not motivated by a deep and abiding desire to inspire social, political or religious change, they might be more likely to 'flip' if threatened with a strict sentence before being offered a plea in exchange for their testimony against their extremist cooffenders.

Use of Confidential Informants

Undercover federal agents and informants were used in 41% of AQAM terrorism cases identified by the Center on Law and Security (2011) in the 10 years after 9/11 and many of these cases were sting operations. The FBI considers sting operations in AQAM cases to be a preventative law enforcement strategy. This practice is controversial, since the operations are often planned by FBI informants (Center on Law and Security, 2011). A defense of entrapment has never been successful (Center on Law and Security, 2011), despite the fact that several AQAM supporters had a history of mental illness. Indeed, 13% of the 210 AQAM perpetrators identified by Freilich et al. (2012) had a history of mental illness. While this bolsters evidence for claims of entrapment, the law enforcement practice of using informants and sting operations continues. Undercover federal agents have had more success with the far-right movement and some (Chermak et al., 2009; Freilich et al., 2009a) have attributed the decline of far-rightist groups to this practice.

CT Training and CVE Programs

CT training currently focuses on the front line or local officers. These officers are trained to recognize terrorism and related crimes, taught how to record observations in a standardized manner, and taught how to share this information with the Federal Bureau of Investigation-led Joint Terrorism Task Forces (DHS, 2012). More than 200 000 law enforcement officers have been trained to record suspicious activities through the Nationwide Suspicious Activity Reporting Initiative. This initiative was created in collaboration with law enforcement agencies and privacy, civil rights, and civil liberties officials (DHS, 2012). CT strategy also includes the "If You See Something, Say Something" public awareness campaign (DHS, 2012). However, this campaign is listed on different DHS documents as linked to the CVE programs.

CVE takes a more community policing approach. It integrates (1) community involvement and "If You See Something, Say Something" (also known as the 'Blue Campaign') public awareness campaign, (2) training programs for local law enforcement, and (3) attempts to reduce support for terrorism by integrating immigrant populations and reinforcing American ideals/culture (DHS, 2012; see also Freilich and Chermak, 2009a who discuss applying similar strategies to far-right extremists). Although not immediately apparent, goals (1) and (3) can be incongruent: encouraging community members to be vigilant against terrorist supporters risks radicalizing at-risk immigrant populations who may perceive themselves as being unfairly targeted by the Blue Campaign (McCants and Watts, 2012). McCants and Watts (2012) criticized CVE programs for not having a clear definition shared by federal agencies. For example, DHS classifies CT and CVE training programs as distinct, however, the tactics used by both are similar – community involvement that risks ostracizing immigrant populations. Further, the increasing use of informants and sting operations (Center on Law and Security, 2011) could possibly undermine privacy, civil rights, and civil liberties of individuals. Thus, current CVE programs, which focus on potential suspects and sting operations, may at times increase radicalization among AQAM supporters (McCants and Watts, 2012). These strategies may be incompatible with the constantly evolving threats posed by different types of domestic extremists (Chermak et al., 2009b).

The points raised by Chermak et al. (2009b) that CT training programs tended to ignore the relative risks posed by different elements of the domestic extremist movements and primarily focus on AQAM supports remains valid even after the 2011 updates spearheaded by DHS. Both the "If You See Something, Say Something" public awareness campaign and attempts to integrate immigrant populations into American culture (1) ignores groups and individuals in the domestic far-right and environmental and animal rights extremist movements, which also pose a real threat to national security, and (2) unnecessarily risks increasing the radicalization among AQAM supporters (McCants and Watts, 2012).

Domestic Extremists' Offending Patterns and National Security

National security measures need to consider not just the risk of terrorist attacks, but also the criminal trajectory and offending patterns of extremist groups. Since there is widespread disagreement by academics and law enforcement about what constitutes terrorism (Schmid and Jongman, 1988; Chermak et al., 2010), obtaining reliable counts of acts of terrorism is extremely difficult. Lack of reliable data is detrimental to the creation of sound anticrime policies. According to Chermak et al. (2010), domestic extremists commit crimes that vary in magnitude (from nonviolent financial crimes, to brutal hate crimes, and bombings that cause millions of dollars in property damage and countless lives lost) and motivation (e.g., greed, anger, hate). These must also be considered to assess the risks to national security and design appropriate countermeasures. Further, as noted by Chermak et al. (2010), limiting the focus to acts of terrorism also ignores the many precursor crimes that extremists commit to fund their operations and terrorist attacks. These precursor crimes provide opportunities to law enforcement and the criminal justice system to identify extremists and to engage in general and specific deterrence before they engage in an act of terrorism.

Law enforcement actions and civil suits by the government and nonstate actors – such as watch groups – have been known to cause the decline of specific extremist groups (Chermak et al., 2009a; Freilich et al., 2009b; Smith, 1994). Skinhead groups declined in the 1980s due to a combination of 'aggressive federal criminal prosecutions and private civil rights attorneys,' which targeted key personnel (Smith, 1994: p. 91). For example, Richard Butler, the leader of the Aryan Nation, was forced into bankruptcy because of a civil suit in 2000, which lead to the decline of the Aryan Nations as many members defected to other far-rightist groups or formed their own groups.

Research has found that routine traffic stops involving far-rightists can escalate into a violent incident, or even fatality (Freilich and Chermak, 2009a). In addition to deaths or injury caused by the incident, escalation can have far-reaching consequences, e.g., it can radicalize many less extreme far-rightists who become aware of the incident or further radicalize the individual(s) involved in the violent incident (Chermak, 2002). However, the risk of a routine stops escalating into a dangerous incident is not consistent among all members of the far-right. For example, not all militia groups pose the same degree of threat. Duffy and Brantley (1997) created the Militia Threat Assessment Typology, which divides militia groups into not dangerous – category 1 to 2 – and groups that pose a major threat – category 3 to 4. There are also gradations of risk to the public among skinhead groups. Hate motivated skinhead groups tend to commit acts of violence against minorities and are more dangerous, while criminally motivated skinhead groups engage in illicit financial schemes for profit (Chermak et al., 2009b). Chermak et al. (2009b) recommended that law enforcement officials pay more attention to the more dangerous groups to maximize their desistence efforts.

The risk of escalation can be reduced by a combination of nonconfrontational dialogue by law enforcement officials and law enforcement training (Chermak et al., 2009b; Duffy and Brantley, 1997). The former humanizes law enforcement officers, while the latter would help officers to identify far-rightists (e.g., driving with no/strange license plates and referring to himself or herself as a sovereign citizen are indications for far-right ideology) and distinguish between those who belong to high threat groups, as opposed to a group that poses a minor threat. Appropriate law enforcement training would also aid in intelligence gathering (Chermak et al., 2009b). Appropriate law enforcement training would increase the likelihood that officers would know which questions to ask to determine the level of risk posed by the far-rightist. Such intelligence can then be shared with other law enforcement personnel (Chermak et al., 2009b).

Law enforcement should also pay closer attention to older extremist groups. Caspi et al. (2012) found that older far-right groups accounted for more homicides than younger groups. Older groups also had more connections to other groups (Caspi et al., 2012). A focus on networks of groups in the far-right movement would provide opportunities to law

enforcement: arrest of key personnel in older, more connected groups could have more wide reaching deterrence and desistence effects, when compared to arrest or conviction of members of less connected groups.

Conclusion

This article provided an overview of the three domestic extremist movements that pose the greatest threat to national security. However, these threats are dynamic and national security policies need to be sensitive to the overall criminal offending patterns of specific movements and the characteristics of the specific movements and its supporters. Although recent DHS-led CT polices were created in consultation with civil liberties and civil rights organizations, the lack of evidence of extremist ideology among many individuals prosecuted on AQAM cases suggests a net widening strategy that risks radicalizing alienated individuals in migrant communities. Recent DHS-led CT stated goals to counter domestic extremism and its practices that target primarily supporters of AQAM risks ignoring the threats posed by the far-right and far-left, namely environmental and animal rights extremists. Suggested amendments to national security CT efforts include widening the scope of law enforcement training to include strategies that would help identify other types of extremists, inclusion of extremists in the political process and by providing them with legal avenues to attain social, political, and religious change.

Abstract

Through much of the 1800s and into the first half of the 1900s, the security of a state depended heavily on the balance among its own war potential and that of its adversaries and allies. In the second half of the 1900s that relationship weakened in the context of cold war bipolarity and a nuclear standoff between superpowers. The relationship is changing again in fundamental ways at the start of the twenty-first century. 'Globalization' brings an increase in the mobility of goods, ideas, and technologies that multiply the speed with which war potential changes, and erases many of the boundaries that linked security conceptually to the war potential of *states*. Research aimed at understanding the war potential of *situations* covers some of these changes, but not all. As the ability of diverse political units to produce and deploy organized violence for political ends spreads, behavior that in the past might have been thought of as terrorism, will increasingly become more like war. The goal – realistically – might be to undermine the foundations of a state or bring down a government. In that scenario, each important term in the phrase 'national security and the war potential of nations' will have taken on a very different meaning.

Klaus Knorr wrote *The War Potential of Nations* in 1956. This book marks a key transition between different approaches toward the study of national security. Through much of the nineteenth and into the first half of the twentieth century, the security of a nation depended heavily on the balance between its own war potential and that of its adversaries and allies. In the second half of the twentieth century that relationship weakened in the context of cold war bipolarity and a massive nuclear standoff between superpowers. The relationship is changing again in fundamental ways at the start of the twenty-first century. The war potential of nations surely will continue to affect national security, but it will not nearly determine it. More importantly, almost all the terms in that statement are coming to mean very different things than they did in 1956.

Historical Perspectives

In the second half of the nineteenth century, 'war potential' was a narrow conceptual proxy for 'measuring' the military power of nations. The foundations of war potential were the economic and technological resources that could be mobilized for military purposes. This made good analytic sense in an era of industrial warfare – when nations maintained in peacetime a small fraction of the military capabilities that they could mobilize for war by simply redirecting production. World Wars I and II were won by nations with greater war potential, not by those with the advantage of existing forces at the start of the war.

Knorr understood well the promise – both analytic and practical – of being able to measure this potential. If national security were some function of objective measures of power, then parsing out the problem (at least) would be made a much simpler task for scholars and policy makers. He distinguished among three critical components of war potential – economic and technological capacity, administrative skill, and the political foundations of military power. The idea was to calculate war potential: *if* each component could be measured with reasonable precision *and* some arguments about their interactions could be built.

Knorr assessed this enterprise carefully enough to see clearly its inherent limitations. Except in the very few cases where nations use sheer force simply to seize something, the purpose of deploying military power was to influence the behavior of another actor. In all cases of influence there clearly were objective components to power. But these were always and everywhere put into play in the context of relationships or anticipated relationships that had many other components of power. Without using formal models or even 'soft' game-theory metaphors, Knorr wrote in rather precise analytic terms about the importance of information asymmetries, domestic political constraints, reputational effects, and the like in relationships of mutual coercion. He argued strongly that net assessment (the detailed counting and analysis of military forces) was by itself a very weak tool. Without reference to particular objectives and contingencies, to study and measure the war potential of nations would be a fragile approach to thinking about and planning for national security.

These arguments today seem obvious, almost trivial. What was less obvious to Knorr, and remains more difficult today, is how to move the intellectual and policy debate forward. The consolidation of a bipolar power distribution during the middle years of the Cold War, along with the deployment of massive nuclear arsenals that essentially overwhelmed any realistic measures of 'war potential,' made that problem more immediate.

Twentieth-Century Strategy

Thomas Schelling's (1960) work *The Strategy of Conflict* proposed one kind of solution. The new studies of strategy focused much less on the war potential of nations and much more on the war potential of *situations*. It did this by abstracting away from

precise measures of capabilities and even more importantly from precise understandings of the intentions and objectives of an adversary – a major analytic move during a period of time when American policy makers (at least) felt they had a poor understanding of the USSR.

At a time when net assessment was becoming intellectually stagnant (and arguably boring), the turn to 'strategic studies' opened up a new and extremely interesting intellectual agenda for national security scholars to explore. It also pulled into the picture a new set of tools that were developing rapidly in mathematics and economics – in particular, mixed motive game-theory models. The combination of newly configured research questions and fast-improving tools led to an explosion of work that clarified powerfully the strategic logic of situations like nuclear deterrence, brinkmanship crises, and coercive diplomacy.

This knowledge came at a cost, of course. The power of abstract-deductive theory to produce generalizable arguments rests in part on a set of assumptions about the characteristics of the actors or players in the 'game.' It has always been a central disagreement among scholars whether (more precisely, when and under what conditions) the benefits of this approach are worth the cost.

The end of the Cold War sharpens both the intellectual and practical consequences of that disagreement. Bipolarity was a significant clarifying force in international politics – while the Cold War was never as 'simple' as some nostalgic views would have it, it did create a marked explicitness about the major lines of conflict that the twenty-first century so far lacks. The national security environment for many nations, and surely for the USA, is now much more fine-grained than it was in 1965.

Future Directions

The problem with flattening out the past is that it makes it harder to see the future in multiple dimensions without becoming frightened and confused. It may be that the USA has enjoyed a post-Cold War honeymoon since 1990 and that the future will be increasingly challenging and unstable. Of course, there are periods of modern history where linear extrapolations of contemporary trends would have worked tolerably well as a foundation for planning the future – for example, between 1950 and 1975. There are other periods – for example 1925 to 1950, or 1975 to 2000 – where discontinuous changes in world politics, technology, social forces, and the economy radically displaced what were assumed to be core 'realities' of security planning. The period around the start of the twentieth century was such a period. Between 1895 and 1920, applications of the internal combustion engine, electricity, and the airplane – along with the rise of the German nation, social Darwinist ideologies, and decolonization – recast fundamental features of the security environment for nations.

Such periods present two distinct kinds of challenges: to master the technology, and to understand the social, economic, and military implications and possibilities that come with it. National security planners recognize the new uncertainties of threats that are smaller, more diffuse, and likely coming from many different directions. From a theoretical perspective, the strategic approach (to build increasingly sophisticated, generalized models of situations) will need at a minimum to be supplemented with renewed attention to the actors and players in the game.

Questions of National Security

The historic literature on war potential of nations is a reasonable place to start. It forces certain questions: What is war going to be? What potentials are relevant? And are nations still the appropriate central focus for the investigation? The answers to these questions were never clean and simple, and they are becoming far more complex in ways that matter deeply for thinking about national security.

The Meaning of 'Security'

One important complicating factor is simply that security has come to mean much more to many people than the core issues of territorial integrity and political autonomy. The discourse of international politics (both popular and scholarly) now embraces concepts like economic security and environmental security. There may be instrumental political reasons to import metaphors from the security debate into these other important areas of national interest, but there are intellectual costs as well.

The broadening of the realm of 'security' makes thinking and theorizing about it as a dependent variable of anything a much more complicated task. The war potential of other nations would play a small (although not insignificant) part in an analysis of US environmental security. Environmental interests are not necessarily any less important than security interests. But the clarity of focusing on security in a narrow sense as territorial integrity and political autonomy is diluted by stretching the definition. Realists argue that security is a prerequisite for almost anything else that nations want to achieve in world politics. Non-realists may disagree with the vehement emphasis on security. But few doubt that military power is still a critical restraint on the freedom of nations to act internationally, and particularly to act in ways that threaten the vital interests of the possessor of military power.

Globalization and Mobility

A second complicating factor comes from a set of transformations that fall under the rough heading of 'globalization.' More precisely, the ability of political units to produce and deploy organized violence for political ends (an updated notion of war potential) is being deeply affected by changes in the global economic environment.

The simplest way to think about globalization is to see it as a story about the causes and consequences of an increase in *mobility*. For most of human history, neither goods, nor capital, nor most people, nor many ideas moved very far from their place of origin. Over the past several hundred years, mobility of many (although not all) things has increased – unevenly across time and with some setbacks.

Political economists recognize that mobility makes possible the expansion of markets beyond the physical and other borders that previously contained them. There is simply no serious theoretical framework in which security is unaffected by

this change. The war potential of nations effectively stretches beyond national borders in a profound way. This is made more conspicuous by the 'spin-on' phenomenon. The commercial sector now leads the military sector in most key technologies that underpin military power. And the logic of the commercial sector is decidedly not national. The so-called revolution in military affairs (RMA) and particularly the increasing information intensity of military operations (which is part of that revolution) cut in the same direction. Information is inherently more mobile than tanks, airplanes, or almost any physical asset. Of course, it is also harder to secure in most settings than an aircraft carrier or a nuclear missile buried deep underground.

The most significant exception to increased mobility is people. People do not move across borders as readily as other technological and economic resources. This may be a key national factor of power that nations still control or contain – although it is not clear for how long that will remain the case. In any case, national security concerns about the increased mobility of people may complicate economic globalization as well as vice versa. Technology can be anywhere, but people still have to be somewhere, and where they are may matter a great deal for individual nation states. The current US lead in information technology owes a great deal to Indian, Taiwanese, and Israeli engineers and entrepreneurs who have immigrated to the USA (or come temporarily on H1B visas) and maintain strong network links to evolving technology clusters in their home nations. At some point nations will experience in a much more acute way the tension between the mobility of people who carry key technological talent and the 'national' security implications of allowing that talent to cross borders freely.

In addition to mobility (which has increased markedly in the past, most dramatically during an earlier period of 'globalization' at the end of the nineteenth century), the next phase of globalization is also about a dramatic increase in *speed*. The digital revolution is reducing the cost of moving a piece of information around the world in real time to near zero. Big, heavy things move much faster as well because they can be moved more intelligently with the use of information. This is unsettling to humans, who think and act slowly. It is even more unsettling to political organizations, because aggregating a bunch of slow humans into a polity usually makes them even slower. An increasing number of those polities now have some form of democratic decision-making system which has the effect (indeed, is designed explicitly in some ways) to slow things down even more.

This disconnect in speed will have profound implications for national security. There is a straightforward and narrow version of the argument. If wars will be faster – that is, time limited by military technology and by the constraints of democratic control – then existing forces may once again become a more important determinant of who wins than 'war potential' in a deeper sense. Yet there are inherent strains – and not just fiscal ones – for democracies maintaining large existing forces during peacetime.

There is a broader version of the argument as well. Balances of power have been an important stabilizing factor in international politics because balancing behavior has prevented the consolidation of hegemony by an aggressor nation. But balances do not form quickly. Napoleon nearly conquered the European landmass before an effective balance formed against him. The Grand Alliance did not fully come together to oppose Hitler until 1942 – quite late in an offensive that actually began almost a decade before. When competing systems move at increasingly asymmetric speeds, the results are likely to be unstable and surprising. Balance of power both as theory and practice has been an important part of the relationship between national security and the war potential of nations. Yet balances may become less stable and more volatile in the future than nations expect.

Size of the War Machine

A third complicating factor, loosely connected to globalization arguments, is the issue of *size*. The tools of large-scale organized violence are getting smaller. Nuclear weapons were the first modern step in this process, but they were hard to engineer and build, even for large nations. Biological weapons are different: a biological agent can be microscopic. More importantly, the equipment to produce custom-designed virulent biological agents will soon be available in suitcase size for US$10 000 or less. An effective computer virus may be even easier and cheaper to manufacture. In more than 50 years no subnational group has yet gained possession of and 'used' a nuclear weapon (including in a bargaining situation) for political purposes. Almost certainly it will not be possible to say the same of the next generation of weapons of mass destruction or disruption 50 or far fewer years hence.

Conclusions

Perhaps this kind of capability does not represent war potential in a traditional sense. One conclusion to draw from this is that it makes sense fundamentally to rethink the term itself, as well as the range of actors who can possess war potential. Changes in mobility, speed, and size have dramatically increased the porosity of national borders. Given that porosity, behavior that in the past might have been thought of as terrorism could increasingly become much more like war, in the sense that the goals of the behavior might not simply be revenge or the placing of pressure on a particular, discrete policy. The goal – realistically – might be to undermine the foundations of a nation or bring down a government. In that scenario, each important term in the phrase 'national security and the war potential of nations' will have taken on a very different meaning.

Editor's Note

Security and security studies in the twenty-first century are discussed in Alan Collins (2013), Collin S. Gray (2011), Jonathon R. White (2012).

National Socialism and Fascism

Italian Fascism and National Socialism signify a new type of political mobilization, which came into being after the end of World War I. Both movements were ideologically influenced by integral nationalism and racism but drew their specific political impetus by exploiting the widespread anticommunism and antisocialism among the bourgeois strata of postwar society. Italian Fascism in particular was taken as a model by comparable movements all over Europe, but, with the exception of that in Spain, only Italian Fascism and National Socialism were able to establish a dictatorship.

Italian Fascism

Origins

The origins of Italian Fascism are closely connected with the internal weakness and lack of legitimacy of the liberal regime reflected in a series of protest strikes and factory occupations by rural and industrial workers. Hence, Giovanni Giolitti tolerated the use of violence against organized labor by the fascist *Squadre d'azione*, which resulted in the emergence of a dualistic power structure. It was reflected in Gabriele D'Annunzio's expedition to Fiume in 1919 as well as in the actionism of the Blackshirts terrorizing the countryside and socialist communities. Benito Mussolini seized the opportunity to establish the veterans organization *Facio de Combattimento* and to shape it into a nonartisan mass movement, which he reorganized in November 1922 as *Partito Nazionale Fascista* (PNF). By threatening the governing liberal cabinet by activating the revolutionary potential of quadrism and by unleashing the march on Rome on 27 October 1922, Victor Emmanuel III installed him as Prime Minister in a right-liberal coalition cabinet, although the PNF controlled only a minority of seats in the parliament.

Fascist Dictatorship

Mussolini used his new position to establish his personal dictatorship by skillfully extending the prerogatives of the Prime Minister through legal means. By an ostensibly manipulative reform of the electoral system, he attained an overwhelming parliamentary majority for the governing coalition in the 1924 elections. By a series of 'fascist decrees,' the civil liberties, the freedom of the press, and the space of action for the parliamentary opposition, which formed the antifascist Aventin, were severely curtailed. The ensuing Matteotti Crisis provided a pretext to dissolve the opposing parties and to promulgate a one-party state relying on the extraparliamentary power of the Fascist Great Council. Mussolini thus managed to maneuver both the cabinet and the parliament – which in 1938 was reshaped on a corporatist basis – into the background. The introduction of the fascist calendar and the adoption of the fascist emblems as state symbols completed the creeping process of shaping a fascist state. Mussolini achieved this by carefully evading open clashes with the constitution and achieving a *modus vivendi* with the conservative elite and big business.

Mussolini's tactical flexibility climaxed in concluding the Lateran treaties, which, by comprehensive concessions in social and cultural matters, secured the support of the Catholic Church. The combination of social propaganda and compulsion, as reflected in the program of '*dopo lavoro*,' together with cooperation with big business, enabled him to neutralize the syndicalistic trade unions. The PNF, which in 1943 was composed of 4.75 million members, combined heterogeneous social and political groups and exhibited strong interregional tensions. By isolating the party radicals under Roberto Farinacci, who endorsed the principle of forming a cadre party, the PNF became more or less bureaucratized and was controlled through local and regional administration. Thus, despite terrorist police and the abolition of civil rights by the *lege fascissimi* in 1925–26, the system was not completely totalitarian, particularly in comparison to the Nazi regime. The monarchy, the army, and certainly the Catholic Church preserved a certain independence, and the fascistization of the administrative apparatus was only partially attained. Mussolini's rule relied primarily on a continuous organization of consensus – his domestic policy lacked any clear direction and ideological consistency. The myth of the indispensable role of the Duce for Italian national survival kept everything together, but the disastrous consequences of Mussolini's alliance with Hitler raised resistance among not only the conservative elite and the military but also his own chieftains, who eventually used the instrument of the Great Council to depose him in July 1943.

National Socialism

Origins

The Nationalsozialistische Deutsche Arbeiterpartei (NSDAP) belonged to the series of *völkisch* groupings emerging in the early postwar period in Bavaria, under the impact of the Munich Soviet Republic. The NSDAP originated from the Deutsche Arbeiterpartei (DAP), which was founded by Anton Drexler and Karl Harrer and affiliated to the völkisch Thule Society in Munich. This was a clandestine affiliation of the Pan-German League, which also founded the German *Völkisch* Protection League (Deutschvölkischer Schutz und Trutzbund), designated to draw the labor class into the nationalist camp. A majority of the NSDAP leadership started its political career in the DVST.

In November 1919, Adolf Hitler found a job as political informant for the Bavarian Reichswehr to which he belonged until 1920. Starting as völkisch propagandist, he joined the DAP, which was still an insignificant splinter party among

a number of similar associations. Backed by a group of influential sympathizers in Munich, he first seized power within the DAP in 1921 and shaped it into a fascist party by enforcing the leadership principle and focusing its activities only on continuous propaganda, which connected the fight against the Versailles peace treaty with the mobilization of antirepublican resentments especially in bourgeois strata, together with an extremist racial anti-Semitism. Simultaneously, Hitler succeeded in eliminating intraparty elections and debates.

Even with its stronghold in Bavaria, the Nazi party remained dependent on right-wing conservative support. The projected march on Berlin, according to the model of Benito Mussolini in October 1923, with the aim of establishing a national dictatorship under Erich Ludendorff, the former chief of the imperial army and now leader of the völkisch wing of the German nationalists, was postponed. Hitler, who claimed the political leadership of the right-wing opposition and its paramilitary organizations, ultimately decided to act independently from his conservative partners, but the attempt to proclaim his dictatorship and to gain the approval of the national camp by his propaganda march to the Feldherrnhalle on 9 November 1923 failed completely. The indictment of Hitler for high treason and his imprisonment in the Landsberg penitentiary until December 1924 did not impair his political prestige. The prohibition of the party and its paramilitary wing – the *Stormtroopers* (SA) – weakened, but did not eliminate the successor organizations. Thus, Hitler after his premature dismissal was able to restore the NSDAP and to eliminate competing successor organizations. By the formal dissolution of the NSDAP and its reinvention in 1925, he successfully excluded possible rivals and restored the unrestricted leadership principle, while restricting the party activities exclusively to unrelenting agitation.

In 1936, Hitler succeeded in neutralizing the opposition by the Northwestern group of the Gauleiter, which was controlled by Gregor Straβer and originally was supported by Joseph Goebbels. Their intention to modernize the original party program of 1920, which did not comply with the conditions of the stabilization period, was successfully blocked by Hitler who prevented any constructive programmatic debate. Hence, the left wing led by Otto Straβer left the party in 1931; Hitler's leadership no longer was questioned.

Despite the organizational improvements under Gregor Staβer and the extended propaganda apparatus, the NSDAP even in the Reichstag elections of May 1928 acquired just 2.6% of the votes. But in the following years, the NSDAP profited from the accelerating erosion of the electoral support of the bourgeois middle parties. This trend made itself felt already in the local and regional elections early in 1929 and culminated in the Reichstag elections of September 1930, where the party gained 18% of the votes. Only after this breakthrough the NSDAP became a full-fledged mass movement and, therefore, a serious factor in German politics. Composed originally of mainly protest voters and pensionists, peasants, and former nonvoters, it tended to become an omnibus party, with growing support from the upper middle class. This, however, was connected with an extreme fluctuation among party members as well as voters.

The Seizure of Power

The success of the Nazi party at the polls appeared spectacular, but at its peak in July 1932 it attracted no more than 37.3% of the vote and, in November, suffered a visible setback, while in the 5 March 1933 elections it obtained a slight majority only combined with the conservative German Nationalist Party. Thus, Hitler's nomination as Reich Chancellor in the 'Cabinet of National Concentration' on 30 January 1933 by Reich president Paul von Hindenburg was far from being the outcome of the democratic process, being due to informal pressures exerted by conservative interest groups and the army leadership on the Reich president whose spokesman, Franz von Papen, believed that he could control Hitler within the Cabinet by a majority of conservatives. Papen convinced the reluctant president that the Hitler cabinet was virtually a majority government pretending that the Catholic Centre Party would eventually join the coalition.

Hitler by scheduling premature elections used his majority to get rid of the bourgeois encirclement, compelling his conservative partners to accept the Enabling Law of 23 March 1933. This law, together with the emergency powers of the Decree for the Protection of People and State issued on 28 February after the burning of the Reichstag, invalidated civil liberties and legalized sanctions against the socialist and communist opposition, thereby paving the way for unrestricted dictatorship.

In the first phase of his chancellery, Hitler was preoccupied with the consolidation of his power through a systematic policy of Gleichschaltung (coordination) of public and private institutions: subduing them to party control and placing leading Nazis in high administrative positions without changing the governmental apparatus and its conservative persuasion – except for the installment of Joseph Goebbels as Minister for Public Enlightenment and Propaganda. The radical wing of the party, especially the huge paramilitary organization of the SA under Ernst Röhm, who called for a 'second revolution' and demanded to interfere in the economy as well as take control of the armed forces, was neutralized by the events of 30 June 1934, when Hitler under the pressure of the SS, Hermann Göring, and the army command ordered the immediate liquidation of the Supreme SA leaders. This action led his conservative partners to believe that he was basically a moderate and would put an end to the party's influence on the political system.

The Nazi State

After Hitler had successfully eliminated the influence of his conservative cabinet members, he used the death of Reich President Hindenburg in August 1934 to consolidate his power by combining the presidency with the office of the Reich Chancellor, thereby taking over the command of the armed forces, which in order to prove their loyalty swore as the civil servants an oath of personal allegiance to the Fuehrer. In conjunction with the expanding leadership cult, Hitler disliked to cooperate with the Reich cabinet whose meetings lost their former significance and were finally canceled at all. The contact with the resorts lay in the hand of the Reich Chancellery serving as a clearing agency between Hitler and the governmental apparatus. Actually, Hitler showed less and less interest in

day-to-day politics and refrained from interfering in internal disputes insofar his personal prestige was not involved. Instead of using governmental institutions, Hitler preferred to meet his decisions on the basis of informal information supplied by frequently irresponsible advisers, whereas the Reich Chancellery, the task of which was above all to coordinate the departments, was circumvented by an increasing number of ad hoc agencies established between party and state and derived their authority from Hitler himself. Besides the Stormtroopers (SS), which took over the complete police apparatus, the German Labour Front, which copied the role of the former trade unions, as well as Hermann Göring's Four Year Plan Office were not controlled by the central bureaucracy.

Hence, the Nazi system of government was not at all signified by any 'unity of will' or clear-cut subordination patterns, but by the principle of unlimited freedom of action for the individual position holders, as long as they did not tangle Hitler's personal prestige. Therefore, this system of 'government without administration' instigated a quasi-socio-Darwinist struggle between competing agencies and never-ending personal rivalries among the party chieftains. During the so-called combat period, this system favored the party's dynamism. In the regime phase, where mere propagandists' mobilization became obsolete, internal rivalries and competition turned out to become counterproductive and utterly detrimental for any regular decision-making process, resulting in an accelerating cumulative radicalization. In the long run, the system implied growing disarray and self-destruction. This was supported by the ambition of the party chieftains after 1943, to takeover an all-embracing political control and to continue des party revolution, which had been stopped in 1933–34.

Military Aggression and Racial Annihilation

Analogous to his domestic policy, Hitler dealt with foreign affairs by adapting a 'trial and error' method. Initially he pursued the path of a revision of the Versailles treaty, although being resolved from the start to establish a German hegemony over Europe beyond the territorial limitations of Versailles and to conquer 'living space' (*Lebensraum*) in Eastern Europe. His first step, however, involved breaking the diplomatic isolation of the German Reich, which had been increased by her retreat from the Geneva disarmament conference and the League of Nations in October 1933. By signing the German–Polish nonaggression treaty that ran counter to previous conservative foreign policy, and by concluding a naval agreement with Great Britain, Nazi foreign policy succeeded in undermining the Stresa Front. Despite conflicting interests with respect to Austria's independence, Mussolini entered the Axis alliance in 1936 and joined the Anti-Comintern Pact thereafter.

The domestic corollary of the transition to active foreign policy lay in stepping up the clandestine rearmament, which was already on the way before the seizure of power. Financial and economic policies both gave overall priority to rearmament, culminating in 1936, when the Four Year Plan required the German army to be capable of waging war within a period of 4–6 years. The remilitarization of the Rhineland as well as the introduction of conscription in 1935 was also accepted by the Western powers, despite the fact that they obviously violated the demilitarization provisions of Versailles. The Western powers still believed it was possible to reach an agreement with Hitler and tame his territorial ambitions, even after having acceded to the annexation of the Austrian Republic in March 1938. Not November 1937, but the spring of 1938 became the climacteric of the progress toward open aggression. Although Hitler had played a rather passive role in the Austrian crisis (which had been pushed ahead by Hermann Göring), he was resolved to settle the Sudeten conflict by military means, and his decision to take over the war ministry himself enabled him to act. Neville Chamberlain's decision to continue the policy of appeasement and Mussolini's mediation forced the dictator to reluctantly accept the provisions of the Munich conference in September 1938; however, any expectation that the cession of large parts of Czechoslovakia would curb Hitler's aggressive appetite proved to be utterly wrong – as was proved by the conquest of independent Czechoslovakia and the establishment of the Reich protectorate Bohemia–Moravia in March 1939.

The remilitarization of the Rhineland as well as the introduction of conscription obviously contradicted with the demilitarization provisions of the Versailles peace treaty, but the Western powers did not intervene, still believing that is was possible to reach an agreement with Hitler and to accept his assurance that after the unification of Austria with the Reich there would not be any further territorial demands by Germany. The opposite was true. While Hitler had played a rather passive role with respect to the Austrian crisis, which had been pushed ahead by Hermann Göring, he now was resolved to settle the Sudeten conflict by military means. After the Blomberg crisis Hitler took over the war ministry by himself was resolved to go to war this respect to Czechoslovakia. Neville Chamberlain's intention to avoid a military conflict for the time being as well as Benito Mussolini's intervention that had been endorsed by Göring compelled him to accept the provisions of the Munich conference in September 1938. The expectation that the cession of large territories of Czechoslovakia might curb Hitler's aggressive appetite proved to be utterly wrong and did not prevent the destruction of independent Czechoslovakia in March 1939 and the establishment of the Reich protectorate Bohemia–Moravia.

World War II

Different from the First World War, where the responsibility must be ascribed to the major European powers, the Second World War was the outcome of Hitler's policy to gain for Germany the predominance in Europe and even her rise to a world power. After having achieved the destruction of Czechoslovakia, Hitler was resolved to settle the Polish question either by compelling her to become an anti-Soviet satellite or by using military means. The dictator believed that it would be possible to extinguish the Polish Republic before an intervention by France and Britain. This calculation failed, and Hitler became engaged in a two-front war, which he all the time wanted to avoid. The German–Soviet nonaggression pact strengthened the military and economic position of the Reich, and the ensuing occupation of the Benelux and Baltic states and also the defeat of Greece and Yugoslavia, turned the power balance toward the side of Hitler and the axis powers.

The unexpectedly rapid victory over France did not induce Winston Churchill to accept Hitler's allegedly generous peace offer. The German defeat in the air battle over the English Channel and only short-term successes of the Wehrmacht in North Africa led to a military impasse and would in the long run weaken the German strategic position. Hitler tried to overcome this strategic stalemate by attacking in June 1941 the Soviet Union, which he regarded as the British 'Festlandsdegen,' but already the German defeat in the battle of Moscow in December 1941 destroyed any expectation of an imminent collapse of the Soviet Union, and in the other theaters of war, especially in North Africa and finally Italy, the German army was forced into the defensive.

Hitler was resolved to wage the campaign against the Soviet Union as a war of unrestricted racial and ethnical annihilation. The war should lead not only to the defeat of the Bolshevik regime but also to the complete destruction of the Russian statehood and to a systematic ethnic cleaning of wide parts of the Soviet territory in order to provide living space for the German or Germanic settlers who should build the core of Himmler's gigantic 'General Plan' project. At the end, there was not only the loss of the former Eastern territories and up to 40 million people but also the destruction of the German cities by the Allied Bombing offensive, not to talk about the losses especially of Russian soldiers and civilians. The European war ended with the German capitulation on May 8 and 9 after Hitler had committed suicide in the Fuehrer bunker and resulted in a complete debellatio.

Racial Annihilation

Aggressive anti-Semitism became more and more the center of National Socialist agitation since socialists and communists were no longer their predominant target. The boycott of 1 April 1933 should be a starting point for an anti-Jewish mobilization of the population, but remained restricted to the radical wing of the Nazi movement, while the average people remained distanciated. Hence, the boycott had to be finished after 1 day and Joseph Goebbels decided to utilize instead the strategy of legal restrictions against the Jewish population, which climaxed in the promulgation of the Nüremberg Laws in September 1935. The pogrom of November 1938 was the starting point for the systematic expropriation of the Jewish population. Despite the social segregation and economic expropriation of the Jewish population, the economic pressures prevented any further emigration. The strategy of enforcing Jewish emigration reached an impasse in 1939, although it was supported by the regime until October 1941. By the annexation of Austria and Czechoslovakia and the inclusion of Poland and other East European states, the number of Jews within the German power block had been quadrupled. After the Polish and the Russian campaign, the German leadership planned to replace the emigration concept by creating Jewish reservations, at first at Nisco in Poland, finally by the Madagascar plan. All projects of this kind failed due to strategic or technical reasons and were regarded as provisory steps in the road of achieving a 'final solution' after the war. The role of the SS task units in the occupied Soviet territory started with the liquidation of Soviet functionaries and Jews in leading positions, but since August 1941 they would kill all Jews including women and children. The great majority of the indigenous Jews had already been liquidated by October 1941 when the establishment of annihilation camps and the use of gas vans created the technical facilities for the now intended systematic mass murder, now comprising German and West European Jews as well as the Jews living in Poland and the Southeast European countries under German control in the so-called action Erntefest (harvest festival). The systematic murder of all Jews living under German rule was discussed at the Wannsee Conference on 20 January1942 and then implemented by Adolf Eichmann since April 1942.

The 'Holocaust' was not the outcome of a premeditated plan, but resulted from an interaction between the proceedings on the local level and the Reich Main Security Office under Heinrich Himmler and Reinhard Heydrich. There was no need for any formal order by the dictator whose part consisted mainly in instigating continuous radicalization, without being involved in the concrete destruction process for which the close cooperation between the SS, the Wehrmacht, and the civil administration was indispensable. At the end, about 5.3 million Jews were murdered. Although the news of the anti-Jewish atrocities were distributed by the international press and there were many leaks to reveal the fate of their former neighbors, the knowledge about the dimension of the Shoah among the German population was limited, set aside that many Germans tended to repress the Jewish genocide committed by the Nazi regime.

The Dissolution of the Third Reich

The capitulation of the 6th Army in Stalingrad on 31 January 1943 marks the definite turn of tide against the Axis powers. Because of its lack of manpower, ammunition, and technical equipment, the Wehrmacht did not regain the strength necessary to continue strategic operations and was forced onto the defensive. The breakthrough of the Red army at the middle sector of the Eastern front in the summer of 1944 opened its road into the Reich despite unremitting German attempts to stabilize the front. After the Allied invasion of France and the Allied air offensives, the military situation became hopeless, and it was just a question of time until the Reich was defeated.

The artificial prolongation of the fight relied on the total suppression of domestic opposition, since the army had lost its relative autonomy after the abortive putsch of 20 July 1944. Unlike in Italy, there was no institution left that could take an initiative. The renewed efforts of fanatical party functionaries to take over public administration and to urge for fighting to the last man by means of a progressively tenuous hold over propaganda, and a rule of terror by martial law, signified the last phase of the war – during which Hitler and his chieftains in Berlin had clearly lost any grasp on reality. The end of the Third Reich was composed of not only total military defeat but also the complete collapse of its institutional framework.

European Fascist Movements

Fascist movements originated in most parts of Europe during the interwar period, but only in exceptional cases were they

able to exert any great political influence or establish – as in Italy Germany – a regime of their own. Most of these fascist parties never developed into mass movements, especially within the rural societies of Southeastern and Eastern Europe. Only the Romanian 'Iron Guard' and the Hungarian Nimiety Karat Partial ('Arrows of the Cross') achieved temporarily significant popular support comparable to the PNF. In two cases, fascists were able to rule for a limited period: the Stash under Ante Pevely in Croatia in 1941 and the Arrows of the Cross under Fervency Salami in Hungary in 1944 – both relying on the German occupants. The Link Guards in Slovakia were amalgamated in the authoritarian Assemblymen of Josef Tyson and lost their independence. In Austria, competing fascist movements – National Socialists and the Headwear (Home Guard) – attracted considerable portions of the electorate, but were suppressed (like the National Socialists) or became absorbed by the state-controlled Vaterlandische Front (Patriotic Front).

In Britain, France, Belgium, and the Netherlands, as well as in Norway, fascist groups played an insignificant role. In Spain, the influential fascist Falange was tamed by the authoritarian rule of General Franco and lost its original impetus. Similar developments prevailed in Southeastern Europe where parliamentary democracy was replaced by authoritarian regimes with varying populist leanings. The majority of the fascist movements remained splinter parties and stood in opposition not only to the left but also to the ruling conservative forces and could share power only with the support of the German occupants. Those fascist groups that sympathized with National Socialism – such as the Partie Populaire Française of Jacque Doriot in France, the Front Populaire des Rex of Léon Degrelle in Belgium, the Nationaal-Socialistische Beweging of Adriaan Anton Mussert in the Netherlands, and the National Samling of Vidkun Quisling in Norway – exerted only marginal influence, and this was even more true for Oswald Mosley's British Union of Fascists.

Structural Elements

Italian Fascism provided the model for similar movements, especially for National Socialism that copied techniques, symbols, and political strategies from its Italian counterpart. Although some historians reject the use of a general typology of fascism including National Socialism, the similarities between them cannot be disregarded; however, the extremely destructive and inhuman character of the Nazi experiment appears to be exceptional. The varieties of fascism are characterized by their rigorous antiliberal and anticommunist stance as well as by their extreme nationalism and racism, their specific populist ideology, and voluntarist and decisionist political styles. They can be distinguished from right-wing bourgeois parties by their techniques of exploiting resentments and prejudices of the electorate, especially nationalism and anti-Semitism or – as in the case of Italy – racism, for mass mobilization, and of avoiding any choice between contradictory programmatic targets, thus replacing actual political issues by purely propagandists slogans, although many of their goals are similar to those of the bourgeois right.

The 'cult of the will' – the arbitrary pursuit of utopian visions first articulated by Georges Sorel – and the myth of the unity of the people ('people's community') are specifics for the fascist variety of politics that added a new element to the political process. Although the antiliberal and antienlightenment impetus is a general criterion, there exist differences with regard to the degree of parasitic disruption of the inherited state apparatus, which culminated in the National Socialist regime in Germany, caused by their technique of mobilizing nonsynchronous popular resentments and prejudices.

Fascist movements tend to replace liberal organizational principles by means of amorphous personal legacies culminating in the leadership cult. Mass mobilization is regarded by them as an end in itself, even at the price of a chameleonlike propaganda. As genuine protest movements, their membership and constituency are characterized by an overrepresentation of youth, of marginal social strata, and of social outcasts. Frequently, modernization crises provide a fertile ground for emergent fascist movements. They are specifically a phenomenon of the interwar period, although a series of successor organizations did emerge after 1945, such as Peronism in Argentina.

Abstract

Although nations often claim ancient genealogies, nationalism is connected to the need in modern industrial societies for a standardized language, a homogeneous national culture, and an imagined horizontal community. The modern political conception of popular sovereignty identifies the people with the nation-state. Liberal theorists distinguish between civic nationalism as a voluntary fraternity of equal citizens and ethnic nationalism based on natural organic ties of community. From the Americas in the eighteenth century and Europe in the nineteenth, nationalism spread to the colonized countries of Asia, Africa, and the Caribbean in the twentieth century. Besides its political aspect, nationalism has a major role to play in major aspects of modern cultural life in many countries such as language, literature, art, gender, food, sports, etc. While there have been suggestions that postnational formations such as the European Union and the rise of a global civil society are about to supersede the nation-state, there are opposite pressures as well for autarkic economic policies and chauvinistic ideologies.

Most theorists are agreed that in the specific form in which it is known today, nationalism is closely related to the modern state and its politics. Its rise and spread are linked to the need in modern industrial societies for a standardized language, a homogeneous national culture, and an imagined horizontal community. The modern idea of popular sovereignty was expressed in the identity of the people with the nation-state. This in turn legitimized the rise of anticolonial movements as a necessary unfolding of modernity. But at the beginning of the new millennium, the relations of nationalism to the global order, on the one hand, and to the particularisms of ethnicity, gender, and class, on the other, are facing new challenges.

The Modernity of Nationalism

There is a debate about nationalism's age. Some argue that nations are old, built as they often are around histories of ethnic, linguistic, religious, or dynastic solidarity going back several hundred years before the modern era (Smith, 1986). European countries such as France, Portugal, Denmark, Sweden, or Russia and Asian countries such as China, Japan, or Korea are often portrayed as having old and continuous histories in which a well-defined national identity can be easily perceived. The Jewish people are said to have been a nation, distinguished by ethnicity and religion, since Biblical times. Other analysts hold that even when nations claim ancient lineages through such ethnic and cultural histories, the particular combination of elements that gives to a people the distinct form of a nation is always a product of the modern era (Gellner, 1983; Hobsbawm, 1990). Various dates have been suggested as the point of emergence of nationalism as a modern phenomenon. Some say it was the French Revolution, others the independence movements in Latin America, while still others think that it was the German Romantic movement that supplied the crucial ingredient. But it is generally agreed that by the early nineteenth century, most of the elements that would characterize nationalism were in place within the emergent discourses of politics and society in the Western world. Henceforth, nationalism would be a constituent aspect of modernity itself.

One of the doctrines that nationalism has turned into a feature of common sense is that the world is divided into nations, so that every person, under normal circumstances, is born into a nationality. This common understanding is bolstered by such everyday visual representations as multicolored maps of the world, identity documents such as passports, and international gatherings such as the United Nations or the Olympic Games. These representations are built on another modern doctrine that has become a truism – except for Antarctica, the entire landmass on earth is divided up into national territories, each of which is under the unique sovereign jurisdiction of a state. The two doctrines together add up to a moral claim – that the proper form of modern politics is to be found where the political unit of the state coincides with the cultural form of the nation.

It is not difficult to see the strong connections between these doctrines of nationalism and some of the basic tenets of modern political theory. The definition of national sovereignty as the unique jurisdiction of a single state authority over a territory clearly demarcated on maps and recognized by other state authorities had emerged in Europe in the seventeenth century. What was added in the eighteenth century was the revolutionary idea that the true locus of this sovereignty is the people. Following the course of antiabsolutist thinking in the period of the French and the American revolutions, just as there emerged the idea of the citizen as the autonomous bearer of rights, so also was it asserted that the people, self-constituted and self-determining, are autonomous. This doctrine would supply the moral justification for the nineteenth-century democratic national movements in the territories of the Habsburg, the Ottoman, and the Czarist empires. In the twentieth century, with the rise and success of anticolonial movements in Asia and Africa, this would become recognized as the right of self-determination of nations.

The Morality of Nationalism

Although nationalism shares its genealogy with the modern state and its politics, it has not always found moral approval. The grounds of criticism, however, usually lie in ideological

debates that are part and parcel of modern politics itself. A common criticism is based, for instance, on the distinction between those nationalisms that are more voluntarist in their membership, built around institutions that are more like civic associations, and those that are more organic where membership is ascribed by birth into a collective bound by historic ties of cultural community. The former is said to be the more desirable type, since it respects the right of the individual to choose his or her nationality; the latter is likely to place greater value on the community than on the individual and could thus easily lead to xenophobia and authoritarian politics. This is a distinction that is at the heart of liberal theories of nationalism and usually classifies nations like France, Britain, the Netherlands, Belgium, and the United States as belonging to the first type and those of Central and Eastern Europe, Russia, the Middle East, and most of Asia to the second (Kohn, 1944).

Civic nationalism is meant to think of the political community of the nation as a voluntary fraternity of citizens whose rights of equality and liberty find fruition in the nation-state. The organic idea of the nation, on the other hand, seeks a more natural basis of community, such as, very influentially, in the German Romantic notion of a folk united by the historic associations of a common language and shared myths. The former, the liberal would say, tends to be universalist and inclusive in its political vision, the latter particularist and exclusive (Greenfeld, 1992; Tamir, 1993). In actuality, of course, even liberal states subscribing to the universalist values of civic association have gone through much conflict before extending their citizenship to those who were not regarded as part of the 'original' political community – Catholics in the United Kingdom, for instance, or Afro-Americans in the United States – and the debate still goes on in many Western countries over the status of the new immigrants whose race, language, or religion marks them out as different from the 'normal' member of the political community.

Of modern political ideologies, Marxism in its early years strongly upheld the universalist idea of the political community and regarded nationalism as a limited and transient phenomenon, which, if espoused by the working class, would impede the truly emancipatory path of proletarian revolution. The emerging democratic movements in the territories of the Austro-Hungarian empire, however, impelled the Austrian Marxist Otto Bauer to the view that social democrats should support the demand for independent nation-states. Later, in the context of the nationalities question in Russia and the discussions in the Communist International on the colonial question, Lenin argued for the right of self-determination of nations and Stalin proposed a set of objective criteria such as shared territory, language, and history by which nationalities were to be identified (Nimni, 1991).

The Sociology of Nationalism

Quite apart from the doctrinal terms in which nationalists describe their project, sociologists have tried to provide an account of the sociohistorical conditions that produce nationalism. Ernest Gellner has identified these as the conditions of modern industrial society, which requires free movement of labor and goods throughout the national economy, a general and universal schooling in a standard national language, and a rhetoric of equal access to social mobility. The complexity, interdependence, and mobility of industrial life place an unprecedented emphasis on complex, precise, and context-free communication. This tends to destroy both the exclusiveness of premodern elite high cultures and the provincialism of local peasant cultures and produce in their place an increasingly standardized and homogeneous national culture. The transition to some form of modern industrial society, Gellner argues, is unstoppable. Consequently, nationalism too is an ubiquitous feature of our contemporary world (Gellner, 1983).

If nationalism is indeed the product of certain structural features of modern industrial society, why is it that its particular cultural content is so often the focus of such intense ideological passion and contestation? Benedict Anderson has sought to supply the link between the material and the ideological. The nation, he says, is an *imagined* political community. It is imagined, first, in the sense that, although no single member personally knows all the other members of the nation, in their minds they all live in community. It is imagined, second, as a sovereign community, in line with the modern political idea that the emblem of freedom is the sovereignty of the people. It is also imagined, third, as a limited and particular community, because humankind is divided into many nations. Finally, it is imagined as a community – one that creates a deep, horizontal comradeship. This imagining of the nation, however, becomes possible only through certain specifically modern technologies and institutions. The most crucial is the technology of printing, which, in combination with the new production system of capitalism, gives rise to a publishing industry that produces, through newspapers, textbooks, novels, and bureaucratic documents, a national literature in a standardized national language. Newspapers and novels, in particular, make it possible to imagine lives lived in simultaneity with other real and fictional members of the community, convert events happening to other people at other places into events in the shared life of the community, and thus transform an imagined solidarity into the homogeneity of everyday lives. Censuses, maps, museums, and memorials are other important institutions that contribute to the imagining of nations (Anderson, 1991).

Nation and State

The modern form of the nation is both universal and particular. The universal dimension is represented by the notion of 'the people' as the original locus of sovereignty in the modern state and of all humans ('man,' in the original eighteenth-century revolutionary declaration) as bearers of rights. If this was held to be universally true, how was it to be realized? By enshrining the specific rights of *citizens* in a state constituted by a particular people, namely, a *nation*. Thus, the nation-state became the particular, and normal, form of the modern state. It has been argued that if the basic framework of rights in the modern state was defined by the twin ideas of freedom and equality, the often contradictory pulls of these two ideas had to be mediated by two further concepts: those of property and community. Property sought to resolve the contradictions between freedom

and equality at the level of the individual in relation to other individuals. Community was where the contradictions were sought to be resolved at the level of the whole fraternity. Along the dimension of property, the particular resolutions might be more or less liberal; along the dimension of community, they might be more or less communitarian. But it was within the specific form of the sovereign nation-state that the universal ideals of modern citizenship were expected to be realized (Balibar, 1993).

It needs to be emphasized that just as the sovereign nation-state was a sign of the fulfillment of the universal moral values of modern citizenship, so also was it a concrete entity defined by the practical considerations of viable statehood. The former provided the ideological force in the nineteenth century to the revolutionary democratic movements in many regions of the Habsburg and the Ottoman empires as well as to the movements for German and Italian national unification. But the latter became operative when judging the claims of groups that were considered too small or territorially dispersed or politically immature to have viable nation-states. Thus, the Welsh, Sicilians, Bretons, the many small ethnic groups in the Balkans, or a European colony such as Ireland was considered unfit for independent statehood. This highlights the fact that no matter what the specific cultural content that defines nationhood in a particular nation-state, the requirement of undivided and viable territorial sovereignty will always produce national minorities within that state. It also points to another feature that developed through the nineteenth century to become a basic principle of the modern political world: sovereign statehood depended crucially on recognition from other states within an international states system.

The late nineteenth century was a period of the democratization of politics in the Western world, with the expansion of the suffrage and a wider sense of involvement of the working class in national politics, even if in a role of opposition to the ruling classes. Alongside, there also operated a process of producing national citizens, through a rapidly expanding system of schooling, the imposition of standardized forms of the national language, and not the least by inculcating a popular sense of patriotism by celebrating the achievements of its state leaders and armies. There is little doubt that at the turn of the century, popular nationalism in the United Kingdom, France, Germany, Russia, Italy, Japan, and the United States – regarded as the great powers – was deeply implicated in imperial ambitions, colonial expansion, and military glory.

Anticolonial Nationalism

The emancipatory appeal of modern nationalism lay in its association with the universalist moral claims of the modern state. But, as pointed out before, it was also necessarily conditioned by particular claims to viable statehood within an international states system. The anticolonial settler and creole nationalisms of North and South America in the late eighteenth and nineteenth centuries were, in the many ways, of the same type as the democratic nationalisms of nineteenth-century Europe in that the antiabsolutist element was far more predominant and unambiguous than the anticolonial. The interesting and tragic contrast was the failed Haitian revolution of the 1790s, launched by Black slaves and exslaves inspired by the emancipatory message of the French Revolution and crushed under orders from the revolutionary regime in Paris (Trouillot, 1995). The world was not yet ready for the real wave of anticolonial nationalism.

That would begin a 100 years later. Many of the apparatuses characteristic of the modern state, including its bureaucracies, legal and judicial systems, economic institutions, censuses, communication networks, etc., were introduced into European colonies in Asia, Africa, and the Caribbean as technologies of colonial governance. In some British and French colonies, this even included limited representative institutions in which native elites could participate. Equally significant was the introduction into these countries of modern education in European languages, which opened up for a new group of indigenous intellectuals the possibility of imagining a modern nationhood for their peoples, free from colonial bondage. Curiously, the emancipatory claims of modern statehood were used in the nineteenth and twentieth centuries by colonial apologists to justify Western rule over the rest of the world: those backward regions, they said, had to come under Western tutelage in order to introduce them to modernity and prepare them for responsible government. The nationalist movements of Asia and Africa, by contrast, argued that it was precisely colonial rule that stood in the way of their becoming modern and self-governing nations, fully responsible for their own destinies. Not only was self-government demanded in accordance with the universalist modern doctrine, as a natural right of every nation, but a new economic argument was also added to assert that modern colonialism was inevitably accompanied by the economic exploitation of the colony, and hence, political sovereignty was a necessary condition for the removal of poverty and economic backwardness.

By World War II, anticolonial nationalism had become a significant political force in many countries of South and Southeast Asia, the Middle East, and North Africa. While aspiring to fulfill the project of modernity in their own countries, anticolonial nationalist leaders also launched powerful movements of social and cultural reform, but outside the supervision of the colonial state, attempting to assert their sovereignty over an inner sphere of national life even before the political battle over the economy and the state had been won (Chatterjee, 1986, 1993). This was the period when standard national languages were institutionalized and national literature created and canonized, national histories constructed and archives assembled, and religious doctrines and social practices submitted to a thorough modernist scrutiny and reform. The political process of decolonization became rapid and unstoppable after the end of World War II. In many colonies of Asia, Africa, and the Caribbean, independent states were created through negotiated transfers of power; in others, national liberation was won after armed struggle. It was often argued that independence achieved by peaceful negotiation produced socially conservative and politically conformist regimes, whereas when it was won through armed struggle, the structures of colonial rule, themselves founded on violence, had a greater chance of being socially and politically transformed (Fanon, 1963).

Nation and Culture

One of the consequences of the new theoretical understanding of nationalism, introduced by Anderson, has been the explosion of scholarly interest in the deep involvement of nationalism in areas of culture that apparently have little to do with the political contest over nation-states. The histories of language, literature, historiography, art, music, theater, cinema, sports, and such other modern forms of cultural production are being examined for their many connections with nationalist projects – in their formal properties, in their changing contents, and in the institutions that promote and foster them. Alongside, there has emerged a new literature on family, gender, sexuality, religious practices, food, clothes, and other aspects of everyday life that can be shown to have been shaped and transformed by nationalist cultural projects. A recurrent theme in many of these studies is the active role of the nationalist imagination in the gendering of numerous institutions and practices of modern life. Thus, a common feature is the identification of the inner, the domestic, and the spiritual as the domain of the feminine and that of the outer, the public, and the material as that of the masculine. Another is the imagining of women as the bearers of national tradition. There are interesting variations in these structural relations of gender in the case of anticolonial nationalisms (Abu-Lughod, 1998; Altinay, 2004; Yuval-Davis, 1997).

The other aspect of the relation between culture and nationalism that has received much attention in recent years is that of ethnic politics or, in some descriptions, the politics of identity. A distinction has been made, most notably by Anderson (1998), between nationalism in its classical version and the politics of ethnicity. The former, he argues, imagines community in the form of 'unbound serialities,' i.e., the everyday universals of modern social thought such as nations, citizens, workers, bureaucrats, intellectuals, etc. This form of imagining of universal community is potentially liberating. Ethnic politics, on the other hand, is produced by the 'bound serialities' of governmental classifications, such as censuses. They operate by integers – one can be counted only as one or zero, for example, Black or non-Black, Muslim or non-Muslim, German or non-German, and all partial or mixed affiliation must be ruled out. Such serialities are constricting and inherently conflictual. Others argue that the supposed distinction between classical nationalism and ethnic politics is once again a version of the liberal distinction between good and bad nationalism and that they represent not so much a difference of type as the inadequacy of the classical nation-form to properly represent within itself the full range of aspirations for community in modern political life (Brubaker, 2004).

It has also been said that the apparent proliferation of the politics of identity, occurring in the era of economic globalization, is a symptom of the historical demise of the nation-state. The breaking down of trade barriers between nations, the global spread of the new communications technology, and the unprecedented flow of international migrants are making the sovereign nation-form largely redundant (Hardt and Negri, 2000). The European Union has been frequently cited as an example of a postnational formation superseding the constitutional and ideological limits of the sovereign nation-state (Habermas, 2001). This is accompanied by the increasing assertiveness of a global civil society that often considers the sovereignty of existing nation-states as impediments to the realization of universal ethical goals such as human rights. These conditions, some thinkers have argued, are producing the possibility of the emergence of cosmopolitan forms of government as the more acceptable receptacle of modern political community (Held, 1995; Appiah, 2006). However, many of these arguments produced at the turn of the millennium have now come under challenge with the global financial crisis that has led to a resurgence of autarkic economic pressures and chauvinistic movements against immigrants. Nationalism appears to be alive, if not well, in the twenty-first century.

Nationalism, Historical Aspects of: Africa

Abstract

In Africa, nationalism had a tendency to be studied only in the context of modern independent states, by reference to the European paradigm. Nevertheless, as early as precolonial times, true small nation-states had existed, such as the kingdom of Abomey in today's southern Benin, as also the kingdom of Congo in Northern Angola. Another case was the emergence throughout the nineteenth century of large conquering states, Islamic or others, usually based on slave trading, against which preexisting subjugated nationalities reacted. Today, nationalism is often rooted in such a context. As early as the onset of colonialism, the elites among the subjects developed processes of moderate nationalism. In several cases, it turned into struggles for national liberation favoring the emergence of modern nationalism. But recent trends of tribalism reactivate regionalisms inherited from the past. Do they portend the new nationalism to come? In spite of many predictions, this danger appears less serious than a tendency for existing states to generate xenophobia inside their frontiers, even if these states in their current form have been in existence only for a century or so.

Most analyses of the phenomenon of nationalism in Africa were made recently, in the period after independence was achieved. Studies focus on nationalist processes comparable to those which have taken place in Europe, most of them starting in the nineteenth century. The analyses usually began with the era when emerging states started to demand international recognition, as other nations had done earlier. Only recently a few political scientists and historians have given a modest amount of attention to the long history of nationalist movements in Africa (Davidson, 1992; Berman and Lonsdale, 1992). Others have stressed the catalytic role played by the colonial phase (Ranger, 1968; Johnson, 1971; Mamdani, 1996). But Africanist literature had focused primarily on 'ethnic' problems, portraying them as quite different from – even antagonistic to – a 'nationalist' approach. Until recently, no investigator had pointed out that ethnicity can equally be a function of nationalism as much as nationalism was derived from ethnic awareness (Anderson, 1983; Berman and Lonsdale, 1992; Turner, 2000). The widely prevalent view must be considerably revised, because it is the offshoot of a long tradition of biases inherited from the colonial past of ethnographic research (Hobsbawm and Ranger, 1983; Amselle and Mbokolo, 1985; Coquery-Vidrovitch, 1995).

African political history began very early, several centuries before the colonial episode. Therefore, we designate endogenous nationalism antedating colonization as 'older nationalism.' We note that in precolonial days, what we could regard as legitimate small 'nation-states' did indeed exist, although they were not established on the same presuppositions as in the Western world. These preexisting elements were the foundation on which the process of 'modern' nationalism was, more or less convincingly, grafted in the form of independence as defined by international settlements and the United Nations.

With minor exceptions, the African continent has remained independent until very late in history, at least vis-à-vis European powers. Certain limited points on the coast were occupied at a very early date: the port of Loanda in the west and Mozambique Island in the east by the Portuguese; the port of Mombasa on the Kenyan coast, disputed among the Arabs and Portuguese from the sixteenth century; the Senegal island of Saint Louis at the mouth of the river by the French; and Cape Town by the Dutch, starting in the middle of the seventeenth century. A series of coastal outposts was taken in the seventeenth and eighteenth centuries by the British, including Cape Coast Castle on the Gold Coast and, above all, the small Crown colony created in 1807 at the tip of the Sierra Leone Peninsula to receive slaves 'liberated' from ships engaged in smuggling them. However, at least until the 1830s – when the conquest of Algeria by the French began and the occupation of the interior plateaux of southern Africa was commenced by the Boers, soon followed by the British on the coast of Natal (1844) – almost the total population of African peoples lived in independence, except for a conglomeration of east coast territories dominated by the Sultanate of Oman and Zanzibar.

Older Forms of Nationalism

In the past, we come across two forms of 'nationalism': first, the nationalism associated with the institution of actual small nation-states built over a long course of time around a well-defined plan, and the second, associated with the conquering or colonizing forces in the context of sudden emergence of subjugated states that hardly had the time to reorient and instead triggered revolts of preexisting nationalities.

These conquests of states resulted from a series of jihads (holy wars of Islam), which succeeded one another with no interruption in the northern hemisphere from the middle of the eighteenth to the last third of the nineteenth century. They did not arise from nationalism in the usual sense of the term, but they forged a strong cultural bond. This was established in western Africa around the Pular culture (Robinson, 1985). Fouta Djallon is a good example. In this mountainous region containing the sources of the Niger, Senegal, and Gambia rivers, the Muslim Fulbe (advocates of slavery, including shepherds, farmers, and scholars) gained the upper hand over local farmers and indigenous religions. Locally, the main innovation of the Fulbe was using the Arabic alphabet to

 http://dx.doi.org/10.1016/B978-0-08-097086-8.62065-2

transcribe the literature of the Pular language. This led to the popularization of a culture based on educated people who had an awareness of solidarity. Pular migrations all over West Africa helped propagate their feeling of belonging to a common culture. The Pular community, reinforced by Usman dan Fodio in 1804 in northern Nigeria, was thus both an ideological and an economic venture. Its specificity has survived to the present day. The community marvelously managed to resolve the problem common to all Pular theocracies: how to convert a tolerated minority religion, only adopted by chiefs when it seemed to them to be useful, to a religious and imperial state ideology; how to turn a small, strict, geographically isolated Muslim group into a driving force to obtain recognition of western Sudan as Dar Al Islam and so on.

Precolonial Nation-States

Several animist or Muslim states were constituted as a nation much earlier. The oldest examples of these are ancient Egypt and, to a certain extent, Ethiopia from the beginning of the current era. North Africa was reconfigured by the Ottoman Empire: Morocco, Algeria, and Tunisia already had their borders long before the nineteenth century; the first as an independent country, the other two as Turkish provinces. Tunisia and Morocco became protectorates (in 1883 and 1912), Algeria a French *département*. Nationalism was molded in preexisting frameworks in conjunction with the anticolonial struggle, although it triggered reactions in the form of regionalisms established on linguistic and cultural claims. Berber speakers, vigorously repressed by speakers of Arabic in contemporary Algeria, are a case in point.

Outside Islam, the west coast of Africa was experiencing the proliferation of small nation-states at least since the sixteenth century – the term is not exaggerated, as Basil Davidson (1992) has demonstrated, *mutatis mutandis* – if we take this to mean political formations of people who have shared a common history and most often the same language for several generations, or even several centuries and, recognizing the same political system under the rule of a sovereign or chief acknowledged by all, and working to a greater or lesser extent under this authority in the same economic network of productive and commercial activities. Since the time of articulations by Benedict Anderson (1983), we do not hesitate to speak of the genesis of nationalism outside the Western world.

The emergence (toward the end of the seventeenth century), the rise (from 1760 to 1840), and the decline (in the second half of the nineteenth century) of small political organizations focused on slaving – coinciding chronologically with the parallel evolution of the Atlantic slave labor trade, which itself developed simultaneously with the expansion of sugar cane plantations from Brazil to the Caribbean – was no mere coincidence. The establishment of many political organisms correlates closely with the era's dominant international market, at least until the middle of the nineteenth century. The system combined war and trade. During each dry season, the army foraged for prisoners to supply objects of the slave trade. During the rainy season, the soldiers became peasants again, coming back home to toil their lands working in subsistence agriculture.

The kingdom of Abomey (in today's Benin, formerly Dahomey) established a strong political community with a common language and culture, and each generation of children of slaves born on Dahomean soil became Dahomean. This national unity explains why the conquest of Dahomey by the French (1890–94) was the toughest colonial war and the longest in the region. The people of Dahomey gave mass support to the resistance put up by the last king, Behanzin. By the same token, in the heart of present-day Ghana, the Asante Empire, annexed in 1897, did not accept British sovereignty until the Crown resolved, in 1928, to recall the Asantehene and reinstate the sovereign on his Golden Stool, the symbol of national unity.

We could go on and on citing cases of small nation-states which took shape from the eighteenth century onward (Coquery-Vidrovitch, 1999). Other kingdoms appeared during the same period in Central Africa, in the rift lakes region of Rwanda, Burundi, Ankole, and Buganda, where a long collective history had endowed the inhabitants with a common language and, consequently, a common culture. Nationalist excesses in the form of ethnic purges are merely a recent manifestation of a longstanding demographic and political disequilibrium aggravated by the traumas of colonial and postcolonial history.

At the turn of the nineteenth century, the small, militarized Zulu kingdom of Shaka appeared in the northern part of what is now Natal. This realm never submitted to British domination. The last revolt there erupted in 1906. Using this glorious past to justify their political demands paved the way for young militant Christians to found the nationalist Inkatha Party in the early 1920s.

Genesis of Modern Nationalisms

Militant nationalists of the early years of independence attuned their brand of emerging nationalism to the numerous revolts which had developed nearly everywhere during the colonial period. Nevertheless, we should not confuse what have been called 'primary resistance movements' with modern nationalism (Ranger, 1968). Ranger postulated that, slowly but surely, inhabitants of a territory delimited by a colonial power will accept this entity and claim possession of it. By now this 'nationalization' has taken place almost everywhere, despite often poorly understood reactionary movements. A contrasting example is Eritrea, which won its independence for the very reason that Eritrean nationalism has been constructed for a century outside Ethiopia. Ethiopia triumphed in 1896 over the Italian invader, while the province of Eritrea became an Italian colony in 1890, then, as a result of World War II, a British protectorate from 1940 to 1954. The Eritreans never recognized their territory's reversion to Ethiopia, arranged by Western negotiations in 1960.

In sub-Saharan Africa, nationalism engendered by colonialization did not always work out where preexisting nation-states were prevalent. An example is Cameroon, well studied by Mbembe. Another is the Fante nationalism, which developed in the second half of the nineteenth century on the Ghanian coast. Fante communities which had previously existed constituted a sprinkling of small districts, united solely

by language and their occupations because they had long been agents of European merchants on the coast and on privileged terms with the English. Exposed to Western influences more than the rest of the population, they had created a Christianized Creole culture, which made them early adherents of political modernism and aligned them against European intervention from the start. The movement was triggered by British interference starting in 1843. The chiefs, dispersed until then, reacted in 1852 by sanctioning an internal confederation inspired by Western ideas. The Fante Confederation (1867–73) provided for a constitutional regime, with a national assembly of chiefs and an executive parliament. These ideas were propagated by the publication of *West African Countries and People* by the Sierra Leonean physician James Africanus Horton. From 1865 on, to the dismay of the British, Horton advocated the idea of African independence, arguing that the country was more advanced than Liberia 20 years earlier.

A Moderate Colonial Protonationalism

Beginning at the end of the nineteenth century, new economic and social conditions fostered by the conquest provoked an anticolonial reaction of the 'evolved' victims of colonialization. These protests had the paradoxical effect of reinforcing their territorial cohesion within borders which were frequently conceived and imposed entirely by outsiders.

The initial militant nationalists were graduates of missionary schools. The first of these in Sierra Leone were descendants of freed slaves, subsequently known as Krio, which describes both a language and a culture. Others were natives of the Ghanian coast and the mouth of the Niger, often scions of historically dominant classes. A prime example is the Brew clan, established by an eighteenth-century Irish slave trader. His African descendants devoted themselves to trading – first to the slave trade and, when that became impossible, to export commodities. In the second half of the nineteenth century, when British competition was making grave inroads thanks to colonialization, these cultivated bourgeois still sent their children to study in England, or at least to missionary schools on the coast. They bred lawyers and journalists. A dozen of these intellectuals earned PhDs. One Brew was a member of the delegation the Fante sent to Queen Victoria in 1895, when they still believed it was possible to set up a less closed political system than colonial law and order (Priestley, 1969). The next year, three Tswana chiefs traveled from the other end of the continent to London to try to persuade the queen to help their country preserve its independence.

South Africa

African nationalism manifested itself most conspicuously in South Africa. We have already mentioned Zulu regionalism. Another important point is the length of the so-called Xhosa Wars, expressions of resistance which flared up periodically from the end of the eighteenth century to the end of the nineteenth century, reflecting the maturation of a Xhosa awareness among peoples inhabiting Eastern Cape Province. But it was the injection of mining capital (diamonds were discovered in 1867, gold in 1886) that elicited modern forms of black nationalism in the Rand compounds and in Johannesburg. The African National Congress (ANC), ever since the main protagonist of South African nationalism despite several periods of severe repression, was established in 1912. From the start, militant South African nationalists were radicals and often had close clandestine ties to the Communist Party, but most of them were graduates of institutions of higher learning created from the middle of the nineteenth century by various Christian missions (Lovedale, Healdtown, St. Matthew). The first militant feminists appeared on the scene in South Africa and West Africa even before the 1950s. They included Ray Alexander (1941), Ida Mtwana, who assumed leadership of the Women's League of the ANC in 1947, and Liz Abraham, who is renowned for her struggle against apartheid (Walker, 1982).

Evolution From the Years between the World Wars until Decolonialization

It was not until the twentieth century, between the two world wars, that nationalist demands really began to be voiced. This is because severe censorship was never loosened by the French, except by the Front Populaire government (1936). In British Africa the turning point was not until the World War II, when trade unions were first permitted, even before noncolonial political parties. Although its way of life and thinking was more akin to European intellectuals than to the people in local rural communities, the young African bourgeoisie did not wait until the grant of civil rights before demanding, sometimes vigorously, that it be allowed to participate in public affairs. The spearhead of the movement was British West Africa, first centered on Sierra Leone, where an indigenous press developed at an early stage. In the French colonies, political life went on in classical French style in the 'Four Communes' of Senegal (Saint-Louis, Gorée, Rufisque and Dakar), whose inhabitants became French citizens in 1916 (Johnson, 1971). The colony of Dahomey was also a hotbed of protest. There, a merchant bourgeoisie developed alongside the low-ranking civil servants with a French education. It had connections to prominent Afro-Brazilian families and to aristocratic circles of the former kingdoms of Abomey and Porto Novo, and it possessed sufficient financial resources to launch local publications. *La voix du Dahomey*, a newspaper established in 1928 and existing into the 1950s, was its principal mouthpiece. The colonial government was unable to ban the paper, despite a highly publicized trial during the Front Populaire administration.

Nationalists expressed a desire to take the reins of government into their own hands in British-ruled West Africa at an early date. During the 1920s, they obtained the right to participate in municipal government to the extent of voting in local elections. In French colonies, nationalist aspirations were offset for a long time by the French model of assimilation tried out in Senegal: acquiring the citizenship of the colonial power was a way of obtaining rights, based on equality and individual freedom, i.e., everything normally denied to natives, even assimilated groups. In both cases, the political ideal remained reformist. It did not challenge the colonial system. The idea was to fight colonial abuses and to collaborate with the system. This collaboration became a fact after the World War II. Virtually

alone, Dr Danquah demanded the status of a dominion at the Gold Coast Youth Conference in 1940. His platform was still moderate. He advocated the democratization of the legislative council, which then only had nine Africans among the 29 elected members. He proposed a two-chamber system modeled after the British Parliament, one elected and the other composed of chiefs, and he demanded that Africans be granted the right to apply for civil service jobs.

Models, institutions, and trappings of the colonial government fascinated the future leaders of the newly independent states for a long time (Werbner, 1998). Anticolonial radicalism was limited to a very small minority of young Communists, whose militancy had little chance to express itself in Africa. The initial impulse came from George Padmore, a Marxist from Trinidad, who established the Negro Workers Bureau in Hamburg and contacted Lagos militants, undoubtedly thanks to dockers in the port. It was virtually impossible in French Africa and not much easier in Sierra Leone, where the most radical militant was the journalist Wallace Johnson, who established the Sierra Leone Youth League on the eve of the war.

The climate changed only slowly after the World War II. In the French sphere, the nationalist ideas of the elite were sublimated under the cult of Negritude, which was less of a political movement than an ethical ideal. This concept, launched in 1939 by the Antilles poet Aimé Césaire, later author of the explicit indictment *Discours sur le colonialisme* (1955), was developed for the most part after 1947 by the Senegalese poet and politician Léopold Sédar Senghor. In British Africa, intellectuals sued for divorce earlier. They were, nevertheless, likewise steeped in Western culture (the Ghanian Kwame Nkrumah and the Nigerian Azikiwe, future statesmen, had left on the eve of the war to study in the United States, and in 1938 the Kenyan Jomo Kenyata wrote the first thesis in anthropology on his country). But since in the 1950s the British were not yet prepared to budge, the nationalists hardly had any choice but to accept 'multiracialism': one 'race,' one vote, or in Kenya the same number of seats for each of three groups – Whites, Indians, and Blacks – which were nowhere near equal in number.

The Role of National Liberation Movements

Much has been written about the Mau Mau rebellion, the 1952–55 brush fire that swept most of Kenya. It has been argued that the movement was primarily a Kikuyu affair. But the severity of the repression and the blindness of the colonial authorities, whose minds were set in the belief that opposition politicians were the main instigators, contributed to cementing a national, anticolonial sentiment which forced Britain, although victorious on the field of battle, to grant independence (1963). Berman and Lonsdale have written a superb work on the subject (1992).

The anticolonial struggle also formed a national awareness in former Portuguese colonies. After independence (1975), resistance against apartheid South Africa and white Rhodesia sufficed to forge a nation state in Mozambique, a more than 3000-km-long territory which was very disparate at the outset. However, in Angola, the southern Savimbi regionalism was constructed on a partially real, partially manipulated precolonial Ovambo past. This is the case with many contemporary tribalist manifestations; they are exploited primarily for political ends by ambitious, unscrupulous manipulators. For the past 25 years or so it has been demonstrated that one should not lump ethnic group and nation together (Hobsbawm and Ranger, 1983; Amselle and Mbokolo, 1985). But contemporary propaganda resuscitates strong sentiments handed down from the past – for example, the resentment of ravaged peoples against the nations which ravaged them, going back to the black slave trade, as was the case in Angola, or that of social groups dominated and exploited by large landowners of the period, as in the case of the Hutu and Tutsi in Rwanda.

Do these regionalisms of today portend tomorrow's nationalisms? This is unlikely, because in most of the examples we have cited all sides claim the entirety of the country involved. Once again, the struggle against foreign power sparks nationalism. A typical case is the Congo (RDC, former Zaire), where international observers forecast an inevitable explosion. Ironically, it was the widely hated dictator Mobutu who sanctified the national unity of the former Belgian Congo in the name of the national hero and founding father Patrice Lumumba (Turner, 2000).

The risks of regionalist explosions seem to be less of a threat today than do conflicts arising from a chauvinistic approach to nation-states that have become established despite arbitrary delineation imposed more than a century ago (Bayart, 1996; GEMDEV, 1996). The recent Ivory Coast conflict based on an exclusive, xenophobic *Ivoirité* is one of the most ominous signs.

Nevertheless, the partition of Sudan (2011) possibly announces a new era: for the first time, former colonial frontiers reinforced by the Organization of African Unity (OAU) chart (1963) were forgotten, rejected to the past in the name of a general worldwide tendency aiming at regenerating local historical and cultural regionalism.

Abstract

Throughout the twentieth century, Arab nationalism was one of the major political currents in the Arab world, serving as a powerful source of anticolonial struggle and sentiment. The movement of Arab cultural revival (*nahda*) of the late nineteenth century, Arab nationalism of the interwar period and, after World War II, pan-Arabism aiming at Arab unity reflected various understandings of Arab identity, interest, and solidarity. In spite of its secular image, Arab nationalism was marked strongly by (*Sunni*) Muslim references; in spite of the failure of political union, it carried its mobilizing force into the twenty-first century.

For almost a century, Arab nationalism was one of the major political currents in the Arab world; in the 1950s and 1960s, it was undisputedly the dominant one, albeit never uncontested. Like in other parts of what was then still called the Third World, its intellectual origins in Europe did not hinder its spread and success as a principal source of anti-imperialism. Like other nationalisms, it covered a wide range of ideas, images, and aspirations that appealed to and were supported by different social groups and strata; it built on existing self-views and affinities, forming various blends of local, regional, and transnational allegiances, reflecting different shades of religious and secular orientation. Critical scholarship has absorbed key assumptions of the theoretical literature on nationalism and ethnicity more generally, which can be read as a refutation of, or counter-discourse to, nationalist claims and convictions: it stresses the constructedness of Arab like any other identity or identification; its hybrid character rather than the purity of race, culture, language, and design nationalists insist on; fragmentation rather than the unity of intent, action, and objective nationalists assert; fuzziness rather than the clarity of program, boundaries, and orientation they proclaim (Jankowski and Gershoni, 1997; Khalidi et al., 1991; Gelvin, 1998). Arab nationalism thus emerges as multifocal, multifaceted, and multilayered. Measured against the level of theoretical sophistication, knowledge of the historical evolution of Arab nationalism remains highly uneven, and in several respects quite inadequate.

Contingency and Continuity

There was no unilinear movement, or organic growth, from cultural revival (Arabism) to Arab nationalism first in greater Syria and then the remainder of the Arab world, to pan-Arabism and Arab unity. From the beginning, Arab activists interacted, and competed, with advocates of alternative frames of reference that emerged simultaneously in the Middle East and North Africa: if Ottomanism died with the collapse of the Empire, territorial nationalism and political Islam found equally strong resonance among the area's population. While in the Middle East, as in most other parts of the world, there existed a tradition of local pride and attachment that was also reflected in a specific literary genre (*fada'il*) listing the beauties, monuments, and personalities of a specific town or region (*watan*, comparable to the German notion of *Heimat*), this sense of belonging did not necessarily translate into patriotism or nationalism, be it defined in terms of territory (*wataniyya*) or a people/nation (*qawmiyya*). Arabism never constituted more than one option of cultural and political orientation. To insist on choice and contingency, however, cannot imply denying all kinds of continuity between Arabism, Arab nationalism, and pan-Arabism.

Arabism

The intellectual and social roots of Arabism can be traced back to the second half of the nineteenth century, when in the Arab provinces of the Ottoman Empire, more particularly in certain cities of Egypt and the Fertile Crescent, small circles of scholars and intellectuals began to call for a revival or renaissance (*nahda*) of the Arab language, literature, and culture. The Nahda, which in later nationalist writings was represented as an 'awakening' of the Arab nation (*al-umma al-arabiyya*), or of 'Arab consciousness' (*al–wa'i al–arabi*), involved religious scholars, writers, journalists, government officials, and members of the liberal professions, reflecting the spread of education, literacy, and new means of communication, first and foremost an Arab press, that resulted in the creation of a public sphere ranging from clubs and associations of all kinds to salons, tea and coffee houses, theaters, etc. The revival of Arab(-Islamic) culture and literature (in written standard Arabic, *fusha*, not the vernacular used by the vast majority of Arabic-speakers) was to be combined with modern knowledge coming from Europe. While new literary forms gradually developed (novels, theater plays, and later films), poetry retained its central role for cultural and political expression in the Arabic language. The long-held view (e.g., Antonius, 1938) that Arab cultural revival was largely the work of Arab Christians who, through bonds of faith and their education in European schools had been more receptive to European thought including nationalism as it was embraced by their coreligionists in the European provinces of the Ottoman

Empire, has since been challenged and revised (Khalidi et al., 1991; Tauber, 1993; Nafi, 1998). The prominent role of Christians in the early Arab press cannot be denied. However, education on modern lines was not restricted to foreign schools, but equally adopted at Ottoman state schools and private institutions that were established by members of the local elites, Muslims, Christians, and Jews. Most important, Arab cultural revival was at that stage intimately linked to Islamic reform and maintained its link to Islam even later. A second view has been modified (Kayali, 1997): that Arabism evolved as a reaction to a Turkification drive pursued by the Young Turks after their 'revolution' of 1908, resulting in the marginalization of the Arabic language in official use and of Arab delegates in Ottoman representative bodies. The use of Turkish in Ottoman courts, schools, and government offices had been made obligatory since the 1870s. The Young Turks merely accelerated and intensified the centralization policies of the Ottoman reform era (Tanzimat), and as a result Turkish was more widely used in the Arab provinces of the Empire. At the same time, Arabs became less well represented in parliament, the higher echelons of the bureaucracy, and at court. With the decline of a legal and educational system that was based almost exclusively on Islamic learning, whose normative texts were in Arabic, knowledge of the 'sacred language' lost much of its prestige and usefulness for a career in the Ottoman public service. Modernization, then, contributed in more than one way to the rise of Arabism and, later, of Arab nationalism.

Arab political societies that from the 1880s onwards, formed and met in Damascus, Baghdad, Beirut, Istanbul, or Paris mostly worked for greater autonomy within the Ottoman Empire, for constitutional reform or decentralization, not for political independence (Tauber, 1993; Nafi, 1998). Geographically, their horizon was limited to 'greater' or 'natural Syria' (*bilad al-Sham*); Egypt with its distinctive tradition and emerging national movement, Sudan, the Maghreb, and the Arab Peninsula, Hijaz excepted, were not part of their vision. Membership in secret societies such as Al-Ahd (The Covenant, 1909), Al-Fatat (The Young, *c.*1911) or the Ottoman Administrative Decentralization Party (1912) was small; an Arab Congress held in Paris in 1913 was attended by some 25 delegates. Similar to Iranian, Turkish, or Russian opposition groups of the same period, they were made up of urban intellectuals and military officers. In contrast to the literary clubs and associations that also included some women, or addressed themselves to a female audience, they appear to have been exclusively male. Their impact on local society and politics was slight. Still, the secrecy surrounding them and rumors of broad popular support alerted official circles in Istanbul at a time when nationalist feeling was rising not only in the Balkans and among other Christian subject populations like the Armenians, but also in predominantly Muslim territories such as Egypt.

Arab Nationalism

During World War I, the vast majority of Ottoman subjects remained loyal to the Empire. Separatism remained a minority trend among its Muslim population: in 1915, Arab activists in Damascus contacted the Sharif of Mecca, Hussein ibn Ali, a descendant of the Prophet Muhammad in the Hashemite line and *de facto* of the holy city, who, after some hesitation, signaled his willingness to rebel, in the name of Islam, against the sultan-caliph. In a separate move, Hussein obtained British declarations of support for Arab independence under Hashemite leadership in exchange for military revolt. The Ottoman authorities reacted harshly to all stirrings of autonomous political activity including Arabism, which under the circumstances amounted to high treason, and in 1915/16 hanged dozens of activists, creating the first martyrs to the Arab cause. In June 1916, Hussein declared the Arab Revolt and after the fall of Medina in November 1916, proclaimed himself 'king of the Arab lands.' In the course of the years 1917/18, British, Arab, and Jewish forces jointly conquered Palestine and Syria. In October 1918, an 'Arab government' was installed in Damascus under Faisal ibn al-Hussein, one of the Sharif's sons, who with a group of Arab nationalists of diverse origins, attempted to take control of a country ravaged by war, famine, and disease. In March 1920, a Syrian General Congress representing Arab nationalists from Syria, Palestine, and Lebanon proclaimed the independence of 'greater Syria' with Faisal as king. Within Syria proper, their policies were partly assisted and partly resisted by urban, tribal, and village-based popular committees defending their own understandings of collective interest (Gelvin, 1998).

Britain and France were in the meantime taking measures to implement their different wartime arrangements, most of them secret, which included not only the correspondence with the Sharif, but also the Sykes–Picot agreement of May 1916 regarding their respective spheres of interest in the Arab provinces of the Ottoman Empire, and the Balfour Declaration of November 1917 promising British support for the establishment 'in Palestine' of a 'national home' for the Jewish people. The terms of these commitments had somehow to be reconciled; Britain and France did so at the expense of their Arab allies. As a result of World War I, more Arab lands were under European control than ever before, be it as provinces (Algeria), colonies (Aden), protectorates (Morocco, Tunisia, Egypt, Kuwait), or mandates (Lebanon, Syria, Palestine, Transjordan, Iraq) under the newly created League of Nations. Only the Zaidi Imamate of Yemen and the Saudi kingdom in Najd and Hijaz gained or retained full independence. The war and its aftermath defined some of the themes that were gradually woven into the 'grand narration' of Arab nationalism: the crucial role of 'martyrs' for national liberation; the 'Great Arab Revolt' or 'revolution' (*thawra*) of 1916–18 (to be followed by similar 'revolutions' in Egypt 1919, Iraq 1920, Syria 1925–27, the Egyptian officer coup of July 1952, as well as a series of 'corrective revolutions' in the 1970s and 1980s); exposure to 'conspiracies' and intimately linked to it, 'betrayal' of the Arabs by the West.

Within the framework of the emerging Arab state system, Arabism evolved into a political movement of growing impact and complexity, providing one of the major sources of anticolonial struggle and sentiment. The interwar period witnessed the rise of new social and political forces alongside the urban notables that still dominated politics and society (at least outside tribal areas): new urban middle-class parties that could not be considered mere covers for elite families or factions; paramilitary youth movements inspired by the fascist model; Islamic movements of social and political reform; socialist and communist groups, some with links to trade unions, of various

backgrounds and affiliations – all of them responding to Arab references, inflecting their emphases, adapting or rejecting them. If there was a hegemonic formulation of (politicized) Arabism (*al-uruba*) it was provided by *Sati al-Husry* (1880–1968) who as a high government official was able to influence public education in Iraq (then still under British mandate) (Cleveland, 1971; Tibi, 1981). Visibly influenced by the German romantic school, and Herder in particular, Husry defined the Arab nation on the basis of language, history, and destiny, embedding his vision in a narrative of pristine glory, foreign-machinated decline and eventual awakening, with a heavy emphasis on the us/them dichotomy, 'them' being the Arabs' enemies and oppressors from the Byzantines and Crusaders to the Ottoman Turks, Zionist Jews, and European colonial powers. The criteria of inclusion and exclusion remained malleable and contested: Arabness could be interpreted in secular terms to include all men and women of Arabic language and culture regardless of their religious or ethnic background, and thus provide the basis of common nationhood and citizenship; but it was impregnated so strongly with references of a specifically Sunni Muslim nature that it could also be given a distinctly religious (Sunni Muslim) coloring. At the same time it contained enough references to the superiority of the Arab race and genius to make it possible for Kurds, Berbers, or Jews to be marginalized, if not entirely excluded, from the national community.

Pan-Arabism

After World War II, two dimensions were added to nationalist discourse and strategy: Arab socialism addressing the issue of how to organize the growing number of independent Arab states, and pan-Arabism (*al-qawmiyya al-arabiyya*) aiming to transcend the existing regional order. Previous projects of political union had been associated mostly with members of the Hashemite dynasty, who, after losing Syria to the French and Mecca, Medina, and the rest of Hijaz to the Saudis, reigned in Iraq and Transjordan; and they had been restricted to the Fertile Crescent and Arabia (Porath, 1986). The 1930s saw the gradual diffusion of Arab identification to other parts of the Middle East and North Africa. The conflict over Palestine, which in 1936–39 erupted in the Arab revolt or 'revolution,' contributed to widening the sense of a shared Arab destiny. Intellectuals, scholars, and politicians in Egypt, Sudan, and the Maghreb who had not defined themselves previously in terms of Arabness, began to increasingly add an Arab dimension to their agenda, or even adopt pan-Arabism as their ideology. In the late 1940s, the Arab Socialist Ba'ath Party presented the new and enlarged credo of Arab nationalism, revolving around three concerns: unity (*al-wahda*) of the Arab nation both internally and across the existing borders that had been 'artificially' created by the colonial powers and had to be eliminated to create one single Arab state stretching from the Indian to the Atlantic Ocean (*min al-nahr ila l-bahr*); freedom (*al-hurriyya*) from foreign rule and reactionary feudal oppression at home; (Arab) socialism (*al-ishtirakiyya*) which was to be distinguished from Marxism or communism by its belief in God and the rejection of class struggle (Abu Jaber, 1966). The Arab League founded, with British support, in 1945, could at best offer partial fulfillment of this vision: it worked for political, economic, and cultural cooperation among existing Arab states, not for their unification, and it did not adopt Arab socialism (Maddy-Weitzmann, 1991).

In the course of the 1950s, Syria, which until then considered itself the 'beating heart of Arabism,' was overshadowed by Nasserist Egypt as self-proclaimed leader of the Arab nations. The call for Arab unity and solidarity evoked extraordinary responses from broad sections of the population all across the Arab world (the Arab 'masses' constantly evoked in Arab nationalist rhetoric), testifying to the power nationalism, and Arab nationalism in particular, had acquired regardless of its foreign origins. Appeals to Arab solidarity had the obvious function of legitimizing, inter alia, a 'fair share' in 'Arab' oil wealth. The politics of Arab unity equally bespoke the will to control and interfere, in the name of shared Arab concerns, in what rivaling national elites viewed as their domestic affairs. The heyday of pan-Arabism (*c.*1956–67) was also a time of relentless competition among Arab states and intrastate actors (Kerr, 1971). All experiments of merger and fusion (some of them, like Iraq's incorporation of Kuwait in 1990, based on military conquest) failed, most notably the union between the two champions of pan-Arabism, Egypt and Syria, that only lasted for 3 years (1958–61). The failure to solve the Palestine issue, epitomized in the Arab defeat of 1967, was therefore not the only factor weakening pan-Arabism as a political movement of mass mobilization. Yet while, from the 1970s, the 'end of pan-Arabism' was proclaimed repeatedly (Ajami, 1981), not least by the adherents of political Islam and many foreign analysts, reference to Arab identity, interest, and solidarity continued to play a significant role in Middle Eastern politics even at the beginning of the twenty-first century and beyond.

Abstract

Nationalism in East Asia challenged a broad international system known as the Chinese World Order, and modern Japan played the most important role in dissolving this system. In particular, the Sino–Japanese War of 1894–95 and Russo–Japanese War of 1904–05 marked a decisive turning point for the formation of national self-identity in this area. At the same time, a new discourse of Asianism emerged in Japan that had the goal of opposing Western imperialism against all Asian nations by uniting the Asian nations under Japanese leadership. In spite of the lofty principle of Asian cooperation behind the idea, proponents of this concept were never able to take on a point of view critical of Japan's increasing aggression and imperialism. It was not until Japan's defeat in the war in 1945 that these discourses justifying Japanese imperialism virtually disappeared.

Nationalism in East Asia challenged a broad international system known as the Chinese World Order. In particular, nationalism in modern Japan played the most important role in dissolving this system. The concept of the Chinese World Order needs to be unpacked in order to explain this process and the role of Japan in challenging it, which led in turn to the establishment of national liberation movements across East Asia.

The Chinese World Order

The scholar J.K. Fairbank and others (1968) have noted that the Chinese World Order of premodern East Asia was a far-reaching international system characterized by the existence of an emperor considered to have been designated by heaven because of his innate virtue. He was referred to as a 'son of Heaven' and had the 'Mandate of Heaven' to rule. The emperor was considered to rule the world (*tianxia*, 'all under heaven') as a 'child of Heaven,' and his subjects ostensibly enjoyed the benefits of benevolent rule reminiscent of the 'Golden Age' of Chinese civilization described in ancient sacred texts. In reality, the power of the Chinese emperor had a limited reach, and there were a number of foreign tribes on the outskirts of the clearly defined spheres of Chinese civilization. Under the Chinese World Order, however, all subjects were ideally expected to be protected by the emperor, regardless of differences in their race, ethnicity, place of birth, or language – similar to the corpus Christianum of the Middle Ages in Europe.

One basic principle of the Chinese World Order was that it attempted to enfold these foreign tribes in its system and stave off invasion through tributary missions and other rituals. Thus, many foreign rulers from surrounding areas shared and benefited from the common idea of a Chinese World Order. They used the system to their own advantage by sending tributary missions to Chinese dynasties which in turn gave them authority and protection in their own areas. Chinese emperors entered into feudalistic relationships with these rulers under this tributary system, providing them with royal titles, official seal, and a calendar system in return for their loyalty. Foreign rulers, in turn, benefited by securing long-lasting political relations with Chinese dynasties through tributary missions. In addition, the tributary system played a significant role in functioning as a broad network of exchange of people, commodities, and information among different regions (Hamashita, 1990).

There has been academic dispute over when and how the Chinese World Order was developed and maintained. Some argue that it can be dated as far back as the 'Spring and Autumn' and 'Warring States' periods (770–221 BC), while others claim that the prototype of the system can be identified in the age of the Sui-Tang dynasties (581–907), with refinement of the system being completed as late as the Ming-Qing period (1368–1911). These theories notwithstanding, certain characteristics are indisputable: the Chinese World Order constituted one of the primary ways for China to regard its world, and it had a great impact in connecting many disparate and broad regions through their common use of the Chinese written language.

The China-Centered View of China's Neighbors

The philosophy of China as the center of the world (made evident by the Chinese character word for China, 'Middle Kingdom'), which constituted the Chinese World Order, was not always used solely by Chinese emperors. For example, in seventh-century Japan, which was undergoing the formation of a state, the self-consciousness of the people as an independent state was enhanced by their admiration of China and their emulation of Chinese imperial political systems. Later, in the seventeenth century, when the Ming dynasty was destroyed by a non-Han ethnic minority (the Manchus of the Qing Dynasty), a powerful new discourse arose in tributary countries such as Korea and Vietnam which claimed that they, not the Manchus, were the legitimate successors to the Chinese dynasty, given their long history of tributary relations with China.

In Japan, where the tributary system never took root, a number of intellectuals expressed their outright hostility against Chinese civilization, which had entered Japan

through the widespread use of Chinese characters and Chinese literary texts. For instance, in the eighteenth and nineteenth centuries some Confucian scholars claimed that the term 'Middle Kingdom' was meant to refer only to Japan. Other nativist scholars studying Japanese classical literature during the Tokugawa period (1600–1868) claimed Japan was the 'land of the gods,' effectively placing Japan above China. Anti-Chinese sentiment against Qing (Manchu) China prevailed in the peripheral countries such as Korea, Japan, and Vietnam, and played an important role in forming a political and societal basis for national self-consciousness, because of the natural hostility of these nations toward the 'usurper' dynasty (Arano, 1988).

Early modern Japan engaged in the process of forming an independent national consciousness earlier than other East Asian nations. Never having been a tributary of China, Japanese scholars were able to form their own ideology of international relations during this period of relative stability (Toby, 1984). In addition, Japan successfully maintained an individual route for economic trade with Western countries during the peaceful Tokugawa era. In this respect, it can be said that the Japanese state in the early modern age had already begun to separate itself from a China-centered Asia well before the nineteenth century, when the formation of a modern state along the lines of Western nation states was begun.

The Western Threat and the Acceptance of International Law

The Chinese World Order underwent a tremendous change in the nineteenth century when Western nations began incursions into Asia in search of trading opportunities. During the Qing dynasty, a series of wars between Western nations and China in 1840–42 and 1858–60 compelled a small number of intellectuals to promote the urgent necessity of strengthening state defenses. The treaties concluded between China and the Western powers forced China's involvement in the Western nation state system. As symbols of this, the first bureau of foreign affairs, the *Zongli-Yamen* (Office for General Management), was established in the capital city in 1861, and the exchange of permanent missions also began in the 1870s (Bannno, 1964, 1973).

However, high-ranking Qing government officials as well as officials responsible for making foreign policy actually regarded these treaties as an extension of their tributary policy; therefore, they did not regard these new relations with the West as relations among equal, independent nation states, let alone with China as a subordinate. Although Chinese territory was repeatedly invaded, few Chinese were able to reach across societal divisions to form a consciousness of national crisis and national identity. As long as the conventional, historical Chinese view of the world (with China at the center) remained alluring, it was difficult for the Chinese to rally around a nationalism which would necessitate that they actually view their nation as one of many nations in the world.

Meanwhile, nationalism was growing rapidly in Japan – perhaps partially because Japan had never been free of a consciousness of itself as on the periphery of dominant Chinese civilization, and so had long tried to carve out an independent identity. The catalyst for the rapid growth of nationalism and nation-strengthening movements was the Opium War (1840–42) in China, which called Japan's attention to the danger of the Western powers and their interest in East Asia. Japanese nationalism was aimed at strengthening and modernizing Japan along the lines of a Western-style nation state, and to encourage Japan to abide by the system of international law which theoretically supported the formation of a nation state. As soon as the first international treaty was concluded between the USA, the UK, and Russia in 1854, a political movement called *sonno joi* ('revere the emperor, expel the barbarian') was launched to overthrow the bakufu and establish the Emperor as the head of the state. This movement led to the Meiji Restoration of 1868 (*see* Meiji Revolution, The). With the aim of defending itself against the threat of the Western powers, the Meiji government energetically promoted policies aimed at modernizing Japan's industries, military power, and constitutional system. The end goal was to establish a fully fledged modern nation state, with the emperor at its head, which would earn the respect of the Western nations.

Meiji statesmen and bureaucrats learned the principles of sovereignty and the territory through their studies of international laws (*bankoku koho* in Japanese, *wanguo gongfa* in Chinese) which were introduced from China during the late Tokugawa period. Their main goal was to abolish the 'unequal treaties' which Japan had been forced to sign with the West in the 1850s (*see* Peace-Making in History). Japan also sought influence in some East Asian territories in which China had been dominant, such as Taiwan and Korea. Japanese expansionism brought about increasing regional tensions with the Qing dynasty over influence in Taiwan, Ryukyu, and Korea, and the tension finally culminated in military clashes between the two countries.

The Sino–Japanese War of 1894–95 and the Advent of Modern Nationalism

The Sino–Japanese War of 1894–95 was a major catalyst in promoting the growth of nationalism in Japan and transforming the East Asian world order. This war, which broke out over struggles between the two countries over supremacy in Korea, culminated in Japan's unexpectedly thorough victory over China. The tributary system was finally dissolved with the granting of the unconditional independence of Korea, which had been Qing China's closest tributary state. Taiwan also became a colony of Japan. The result was a new East Asian world order with Japan at its center, replacing China.

The mobilization of the Japanese people during the Sino–Japanese (1894–95) and Russo–Japanese (1904–05) Wars marked a decisive turning point for Japan and the formation of national self-identity. In the wake of the Russo–Japanese War, modern Japan began to expand its image of empire with a view to invading the Chinese continent, since Japan was given rights and interests in Korea and Manchuria as part of the spoils of war. The war united patriotic militarists and also promoted an unprecedented sense of alliance among people in Japan from different regions or social classes.

China's defeat during the Sino–Japanese War was a tremendous shock to the Chinese. Moreover, the sense of crisis in China was intensified by the fact that a small country which had long been regarded as a backward area unexpectedly defeated the Chinese army with military power adopted from Western civilization. It was at this momentous time that a true sense of Chinese nationalism first appeared as the old Chinese World Order finally was dissolved. In particular, the news on the military defeat of China rendered the serious impact on lower level bureaucrats and progressive intellectuals, and they attempted to promote nation state building along the lines of Meiji Japan. Although this reform movement (*bianfa*) failed in 1898 under the pressure of conservatives, the Qing government attempted their own top-down reforms, and the transition to a modern constitutional state was launched on a large scale during the first decade of the twentieth century.

During this period, efforts to build up a nation state were also being made in the former tributary countries such as Korea and Vietnam, especially among the lower stratum of elite. In Vietnam and Korea, nationalism came into being through anti-imperialist movements against France in the case of Vietnam and against Japan in the case of Korea. Taiwan's nationalistic movement was born when the Taiwanese opposed Japanese colonial discrimination during the 1920s under the influence of Wilsonian ideas of national self-determination prevailing since World War I. Decades later, a separate form of nationalism in Taiwan gained strength that was based upon a consciousness of Taiwan as separate from the Chinese continental government.

Nationalism and Asianism

As mentioned earlier, modern Japan was the first East Asian country to create a unified nation state successfully, and it struggled to build up a national identity under the strong outside pressures of Western forces and with the new common national goal of 'leaving Asia, entering Europe' (*Datsu-a nyu-ou*). However, the nationalism of the expanding Japanese empire that had already incorporated Okinawa and Hokkaido in its territories took on a new form when Taiwan and Korea were colonized by Japan in 1895 and 1910, respectively. A new discourse of Asianism emerged that had the goal of opposing Western imperialism against all Asian nations by uniting the Asian nations under Japanese leadership. This ideology led to new complications owing to the variety of ethnicities and national loyalties that existed in East Asia (Takeuchi, 1963).

One example of an Asianist thinker was the Meiji intellectual Tokutomi Soho (1863–1957), who promoted an idea of democracy among the common people (*heimin-shugi*) that also stressed the importance of a strong power in Asia to oppose Western powers. He was particularly provoked by the Triple Intervention of Russia, France, and Germany in 1895, which was perceived as the ultimate example of Western arrogance against Japan.

Asianism would only succeed if it accommodated itself to the new regional order, which was constantly changing in response to factors such as the gradual worsening of Japanese–Chinese relations and global changes in the wake of World War I. The possibility of Sino–Japanese cooperation against the West seemed stronger with the publication of works such as Sun Yat-sen's *Greater Asianism* in 1924 (Sun, 1986).

However, in spite of the lofty ideals of the building of a new East Asian order, the Manchurian Incident of 1931 and the start of the Sino–Japanese war in 1937 meant that the autonomy and unification of the Asian nations was not brought to fruition. Certainly, right after the outbreak of hostilities, the idea of 'East Asian Cooperativism' differed from other philosophies such as liberalism or communism as it attempted to promote a principle that would unify Asia during this period of total war. Such ideas were an important test of the possibilities of redefining the traditional boundaries of the state and its people. They were also a criticism of self-serving Japanese policies toward China and of the general attitude toward Chinese nationalism. These were a new manifestation of the possibilities of the principle of Asianism (Hasikawa and Matsumoto, 1970).

However, aggression continued to maintain a stubborn relationship to unity within Asianist thought. The constantly expanding battlefront and the continued use of military aggression against Asian peoples eventually destroyed the hope of Asian unification. Euphemistic slogans such as 'Liberation of the [Asian] people' or 'Building a new order' inevitably became fodder for Japan to deceive itself and justify aggressive war against its neighbors. The wartime concept of the 'Greater East Asian Co-Prosperity Sphere' (*Dai to-a kyoei ken*) was another manifestation of pan-Asianism. In spite of the lofty principle of Asian cooperation behind the idea, proponents of this concept were never able to take on a point of view critical of Japan's increasing aggression and imperialism. It was not until Japan's defeat in World War II in 1945 that these discourses justifying Japanese imperialism disappeared.

Ethnic Nationalism in the Periphery

The Qing dynasty dissolved in the wake of the Revolution of 1911. The new Republic of China aimed at establishing a highly centralized state that would embark on a number of industrial, societal, and educational reforms. Rural skirmishes with warlords and regional military cliques occupied the energies of the government, however, and the unification of the nation was not achieved until the Nanking Nationalist Government was established in 1928. Mongolia and Tibet both virtually declared independence from China on the grounds that the former tributary relationship was severed when the Chinese emperor abdicated in 1912. Undoubtedly, the Chinese central government did not approve of independence, but it was difficult for the government to rule these areas in an effective way since they needed to maintain diplomatic relations with countries such as the USSR and the UK, which enjoyed a number of concessions in those regions. The tendency for non-Han regions to distance themselves from the central government grew stronger (Mancall, 1984). One such example could be found in the independence of the 'Outer Mongolia' in 1924.

During the 1930s and 1940s, there were a number of political movements for independence by Muslims of Turkish descent in the area of East Turkestan (Xinjiang province), as

well as military disputes between Tibetans and Chinese in the co-habitated areas of Tibet. Although areas such as Inner Mongolia, East Turkestan, and Tibet were merged into China under direct governmental control when the Peoples' Republic of China was established in 1949, ethnic nationalism in these areas reportedly has become increasingly vigorous in recent years (Mori, 1998).

Abstract

This article surveys the origins of nationalism in South Asia in the nineteenth century under colonial rule, its many strands induced by multiethnicity and ideological differences. The emergence of two successor states, India and Pakistan, as the end product of nationalist developments and the breakup of Pakistan into two states are discussed. Also discussed are resulting postcolonial developments and the various mutually contested explanations of the phenomenon.

Nationalism, which first developed in the West as a conscious political ideology, spread to other parts of the world in the course of the nineteenth and twentieth centuries. It sustained political and social-cultural movements of great power in South Asia, i.e., the Indo-Pak subcontinent. The ethnic diversity of the region, the responses to colonial rule which subsumed and overlapped with reactions to the encounter with Western civilization, as well as the shifting definitions of national identity determined by the region's history both under colonial rule and after decolonization, gave nationalism in the area a very distinctive and at times highly idiosyncratic character. The purpose of this article is to identify these diversities, explain their nature and origin, and trace the outlines of their history over time. It will also discuss the wide variety of approaches to the phenomenon which will define and explain it in fundamentally different ways.

Origin and Development of Nationalism in South Asia

The Pan-Indian Scene in the Nineteenth Century

One major consequence of the British rule in India was the unification of the subcontinent under one centralized political and administrative authority, even though two-fifths of the territory remained under the rule of Indian princes who accepted British paramountcy but enjoyed autonomy in all internal matters. A second development, crucial to our understanding of nationalism in the region, was the growth of a class of people who assisted in the functioning of colonial rule as middle- or low-level functionaries or found new means of livelihood like law, modern medicine, journalism, or teaching in the new Western-style educational institutions. This 'colonial middle class' soon had a shared language in English and were participants in a common intellectual discourse, facilitated by the new print culture and the modern means of transport and communication. Their colonial experience and exposure through modern education to Western history and socio-political ideas laid the intellectual basis for nationalism and also helped create a shared body of expectations and grievances, which were sharpened by the experience of racist discrimination (see Sarkar, 1989).

A new upsurge in literary and intellectual creativity and movements of social reform, described by some as India's nineteenth-century Renaissance, laid the foundations of what may be described as protonationalist ideology in the first half of the nineteenth century (Majumdar, 1962–63). The researches of Western, especially British, Orientalists fed into these new concerns helping forge the belief in a great and unique past and thence the yearning for a comparable future glory. One essential component of this glorious future was to be a seat of honor in the comity of nations. The latter implied sovereignty, though clear articulation of such bold expectations was late in coming: In the last decade of the nineteenth century only a small group of militant nationalists began to think in such terms (Majumdar, 1962–63). The educated Indians, a small portion of the total population, who began to share the newly emerging political consciousness accepted, for the most part, the fact of British rule as an enduring political reality which would persist for an indefinite period. The responses to this awareness ranged from enthusiastic faith in the redeeming and providential character of British rule, through hopeless resignation, to a desperate longing to try to end it: nationalist ideology could be and initially was, for the most part, strongly proempire.

The Dominant Strand in Indian Nationalism

All-India nationalist consciousness and ideology found an institutional and programmatic base in the Indian National Congress (INC) established in 1885. Initially blessed by the colonial government as a 'safety valve' for letting out any accumulated grievance against the ruler, the INC soon came to be suspected as a potentially seditious organization, despite its repeated avowal of loyalty to the empire at its annual meetings. But soon a militant wing did develop within the Congress and its most prominent leader, B.G. Tilak, declared in his journal, *Kesari*, that freedom was the birthright of humankind (Wolpert, 1989). When the first political murders took place, the government believed that Tilak was the source of inspiration for these acts. Militancy found expression in a mass agitation when the government decided to partition the province of Bengal in 1905 hoping, inter alia, to weaken the political base of the nationalistic Bengali Hindu middle class whom they identified as highly 'anti-British' (Sarkar, 1973). The consequent resentment also fed into the movement for violent action against the rulers which led to local and India-wide conspiracies during World War I and after. The conflict between the 'extremists' and 'moderates' induced a split in the Congress

(1907) which weakened the organization for years to come (Argov, 1967).

The advent of Gandhi, a world figure since his nonviolent campaign in South Africa against the regime's racist policies, led to a transformation of the nationalist agenda after the war. Gandhi, despite his pacifism, had cooperated with the war effort until 1918. But violent repressive actions in Punjab in 1919 and the way the British-sponsored enquiry into these events tried to play these down were major factors in his decision to launch a nonviolent campaign of noncooperation. The aim was to win *swaraj*, i.e., self-rule (Brown, 1972). A major section of Muslim opinion in India had been alienated by the way the Allies treated their religious head or *Khalifa*, the Sultan of Turkey. The mass movement launched by Gandhi brought in these disgruntled Muslims who sought justice for the Khalifa (Hasan, 1991). One strikingly new feature of this agitation, known as the Noncooperation-Khilafat Movement, was the technique of *satyagraha* or nonviolent struggle which had strong ethical overtones. For Gandhi, the struggle was not merely a campaign to achieve independence but an 'experiment with truth,' the moral purpose being for him at least as important as the political goal, if not more so (Gandhi, 1948). Following a very violent action by the supporters of the movement, he suspended it in 1922. This brought to an end the Khilafat Movement as well, and with it the unity in a common struggle which brought the nationalists and militant Muslims together.

Gandhi led one more mass agitation, the Civil Disobedience Movement (1930–34) and in 1937, when the British granted a new constitution to India which conceded a fair measure of power to elected governments in the provinces, the INC gained a majority in most of the provinces, but had very limited support in the Muslim majority provinces. During World War II, India was declared belligerent without consultation with the Indian political parties and the Congress ministries in the provinces resigned. A British mission led by Sir Stafford Cripps failed to secure the INC's cooperation in the war effort. The Congress leadership, including Gandhi, who were planning to launch another mass agitation, were imprisoned in 1942 and a largely spontaneous mass movement, known by a slogan devised by Gandhi, 'Quit India,' erupted. Meanwhile, in 1940 the Muslim League, which eventually won the support of the majority of Muslims in India, launched a campaign for an autonomous Muslim homeland, Pakistan. The Congress leaders were released in 1945 at the end of the war and negotiations with all political parties led to transfer of power and the partition of India into two successor states, India and Pakistan in 1947 (Moore, 1974; Mansergh, 1970).

While the INC under Gandhi's leadership provided a common platform for nationalists of many hues, Indian nationalism was never a seamless web. Firstly, within the Congress, from a very early stage there were the moderates and extremists, i.e., those who preferred the path of constitutional agitation leading to autonomy within the empire and the others who preferred a more militant program aiming at independence. Later, the 'Right' and 'Left' within the Congress represented these two different approaches, except that Gandhi, usually identified with the Right, preferred caution even though he led two nationwide agitations. 'Right' and 'Left' came to subsume a more basic ideological division: the former was in favor of moderate socioeconomic reforms, while the latter wanted a radical program of change undermining the existing status quo. The Congress developed a socialist wing in the 1930s and even the newly born Communist Party of India was allowed to function from within the Congress until 1942 when they opposed the Quit India movement (Majumdar, 1962–63). The tension between the Congress's 'Right' and 'Left' reached a breaking point when the youthful leader, Subhash chandra Bose, felt compelled to leave the party and form a separate organization, the Forward Bloc. Later he left India during the war and, with the Japanese help, formed the Indian National Army (INA). The INA, which participated in the war against the British in the eastern theater of war made a tremendous impact on Indian nationalist consciousness. The British had to abandon the trial of INA prisoners of war in the face of such strong sentiments (Gordon, 1990)

Secondly, while the Muslim support for the Congress dwindled, especially after 1928 when an All Party Conference failed to secure agreement between the nationalists and Muslim parties seeking future safeguards for Muslims in independent India, sections of Muslims remained staunchly loyal to the nationalist cause within or outside the Congress (Hasan, 1991).

Thirdly, India's multiethnicity meant that modern political consciousness had more than one focus. 'Nationalism' often meant a strong sense of local cultural identity and a consequent pride in an imagined ethnic past. In many cases, pan-Indian nationalism could accommodate such 'local nationalisms' as an integral part of the larger identity. There was no conflict between a Bengali, Assamese, or Gujrati sense of past glory and present loyalty to the language-based culture, and similar sentiments focused on Indianness and an Indian political identity (McCully, 1940; Brass, 1974). The Congress successfully accommodated regional aspirations and managed interregional conflicts of aspiration, both before and after the transfer of power. Only in specific historical circumstances, especially after the transfer of power, did such potentialities of tension and alienation reach unmanageable levels.

Muslim Nationalism and Foundation of Pakistan

The INC and Indian nationalism failed in their effort to absorb one religion-based ethnic identity. In precolonial times, the Hindu–Muslim divide, so called, was a social rather than a political fact. Under the Muslim kings, Hindus always constituted a large, if not the larger, proportion of the ruling class. In the great rebellion of 1857, Hindu and Muslim soldiers, peasants, feudatories, and princes fought together with the ostensible purpose of restoring Mughal rule. In the colonial era, the rulers' policy of securing alliances through the distribution of such resources as they controlled, especially education, jobs, and seats on representative bodies, were often based on an identification of the communities as basic political constituencies. This fact helped politicize community identities: In the case of Muslims this identity was seen to have a pan-Indian dimension. The cultural revival in nineteenth century India focused among other things on a romanticized vision of Islam's past glory in and outside India (Pakistan Historical Society, 1957–[1970]).

As Indian nationalism's image of the past focused initially on Hindu achievements and often portrayed the rule of the

medieval Muslim dynasts as an age of slavery for the Hindus, the political agenda of the Pakistan movement postulated the theory of two nations, ignoring the multiple components of both the Hindu and the Muslim communities in India, as also the absence of any pan-Indian consciousness in either community in the precolonial period. This two-nation theory was endorsed by some Hindu historians as well who treated the history of the Indo-Islamic era as a period of foreign rule (Hardy, 1972; Page, 1987; Majumdar, 1962–63).

Nationalism in Postcolonial South Asia

In divided India, the power of nationalism in the Indian Union was manifest in the success in bringing all the princely states within the union's boundaries into the union, with the active support of the local populations and the very survival of the union for more than 50 years to date. The local aspirations, often manifested as centrifugal tendencies, have been successfully negotiated for the most part. In Punjab, the aspirations of the Sikh community developed into a movement for independence, but a policy of severe repression and conciliation of more moderate elements has proved successful (Brass, 1994). In the north-east, several local groups continue to fight for secession from India as do the Muslim separatists in Kashmir. But the forces of commitment to a united India appear to be stronger than centrifugal tendencies. A number of ethnic movements in different parts of India are concerned more with the formation of autonomous states within India than with dreams of independence (Baruah, 1999).

In Pakistan, the ascendancy of Punjab and the ruling elite's refusal to accommodate the aspirations of the Bengalis in East Pakistan produced a nationalist movement first based on their linguistic-cultural identity. In 1971, the East Pakistan-based Awami League won an absolute majority in Parliament, but their demand for virtual autonomy was answered by massive repression. This led to a war of liberation, and Indian intervention contributed to the defeat of the Pakistani army. The independent state of Bangladesh was thus born. Some saw in this event the inevitable triumph of ethnicity-based centrifugal tendencies, but perhaps the hamhanded policies of Pakistan's military government were more to blame. The movements for autonomy or secession in Sindh, Baluchistan, and the North West have also perhaps more to do with cynical misrule than spontaneous ethnic aspirations (Khan, 1985).

Differing Interpretations of Nationalism in South Asia

There is no consensus on the nature and dynamics of nationalism in South Asia. The imperialist perception repeatedly emphasized the multiethnicity of South Asian society, implying that a nation state was not viable in the context of this 'society of societies.' In this view, nationalism was the false aspiration of a cynical elite in India who tried to mislead the masses, normally loyal to the imperial connection (Strachey, 1888; Chirol, 1910). Opposed to this was the nationalist self-perception as the upholders of the natural rights of the Indian people: They wrested India's independence from the rulers through sustained struggle; a reluctant colonial power conceded it in slow stages in response to successive waves of mass agitation, unique in their allegiance to an ideology of nonviolence (Sitaramayya, 1946–47). An organization originally confined to the elite gradually brought in the masses through successful propaganda by words and actions. The imperialists, by contrast, projected the notion that they gradually trained up the Indian people in the art of self-government. The delay in handing over power was entirely due to the internal squabbles of Indian politics, especially the irreconcilable aspirations of Hindus and Muslims which eventually led to the partition of India (Coupland, 1944).

More recent interpretations have strong resonances of these older views. A group of historians in Cambridge explained the dynamics of Indian politics in terms of collaboration with the Raj and competition between various indigenous groups for a share in the resources made available to the collaborators. The 'have nots' of such shares took to agitation, and nationalism was the rhetoric of their frustrated aspirations intended to win support (Gallagher et al., 1973). The Marxists explain Indian nationalism as the agenda of the colonial bourgeoisie whose expectations remained unfulfilled under colonial rule. While they successfully secured the support of peasants and workers, their agenda both before and after independence denied the masses their legitimate rights (Dutt, 1940). One version of this interpretation suggests that the class basis of the nationalist movement did expand over time, bringing in the vast majority of the Hindu population, but it excluded significant sections of the masses, especially those at the bottom rungs of Indian society (Pandey, 1978).

The emphasis on ethnicity as a factor which will inevitably undermine national cohesion features prominently in the writings of some observers like Neville Maxwell, who saw in the emergence of Bangladesh the beginning of the process of disruption leading to the inevitable breakup of India and Pakistan along ethnic lines. Radical writers like Partha Chatterjee provide indirect support for this view in stating that the basic loyalty of the masses is to the communities who should be empowered. The state, in this view, is an institution superimposed by the dominant classes to exploit the underprivileged (Chatterjee, 1993a,b). This perception is a logical corollary of the thesis developed by the historians and social scientists associated with the publications entitled the *Subaltern Studies*. This thesis suggests that all studies of nationalism hitherto have focused on the elite groups denying the underprivileged their agency, their role as subjects in their own right. The notion that the elite leadership mobilized the ignorant populace is shown to be false: The masses interpreted the message of nationalism in their own light and participated in the action only when they felt it to be in their interest. And their primary loyalty was always to their community. This thesis has been criticized, among other things, on the ground that the idea of a pan-Indian nation did not come spontaneously to the masses: they learnt it from the nationalist leadership and their propaganda by word and action.

Open Questions and Prognosis for the Future

Some features of nationalism in South Asia are indeed unique. The Indian Union, the world's largest democracy representing a population of which 40% are illiterate, is also the largest

multiethnic state in the history of the world. The comparison with the USSR is invalid, because that state was successor to the Tsarist empire and hence did not represent any voluntary union. The Indian state, on the other hand, was the union of willing partners who voted for such a union through a Constituent Assembly. And the remarkable fact is that despite tensions the union has held together and representative democracy, a system unknown to the region's political traditions, has survived for half a century. In Pakistan, the creation of a state based on the identity of faith was an innovation. That identity has not, however, been able to hold the state together and the democratic principle has also been violated repeatedly by the army. In Bangladesh, there is a persistent tension between the language-based Bengali identity and the emphasis on Islam preferred by significant groups in the country (Ziring, 1992). In both countries, however, the electorate have repeatedly proved their allegiance to the imported ideal of representative democracy.

Crystal-gazing into the future of the South Asian states is not a very rewarding exercise. If there are threats to their survival and risks of breakup into smaller units, one needs to ask whether these arise from irreconcilable ethnicities or from the contingencies of bad government and the exploitation of particular groups by others. How far the problems of poverty and ignorance have inhibited the growth of national consciousness among the masses also needs to be analyzed. Another question which will have to be addressed is the implication of globalization for nationalist ideologies and the nation state itself.

Nationalism, Historical Aspects of: The West

Miroslav Hroch, Charles University in Prague, Praha, Czech Republic

Abstract

The article starts from the premise that nationalism has to be studied in relation to nation: an historical aspect of nationalism is the formation of a modern nation and the creation of nation-states in Europe. The study of the phenomenon, however, is complicated by disparate use of the concept of nationalism by various researchers. 'Nationalism' has thus become a hazy and not very suitable tool for analysis, which is also reflected in numerous misunderstandings in evaluations of both the positive and the negative roles of nation and nationalism in history. This article documents that, despite the considerable differences in terminology and evaluation, there are roughly five fundamental causal relations that the various research schools consider crucial for nation – and nationalism – forming: (1) state-political historical foundations; (2) ethnic roots; (3) processes of modernization, including industrialization, institutional education, and social communication; (4) nationally relevant conflicts of interest and unevenness of development; and (5) psychological and emotional manipulation.

The complicated process of the modern nation-forming and the onset of the manifestations of nationalism has been, quite understandably, a subject of scholarly research ever since the nineteenth century. This research has had to struggle with a number of theoretical and semantic problems, and has not achieved consensus over the fundamental issues of terminology. The question of what role was played by 'nationalism' has been answered differently by different authors, primarily depending on how they defined nationalism, nation, nationality, national identity, and ethnic group – and relations between these categories. Therefore, it is most important to investigate through what terms the authors analyzed the processes and how they defined the terms.

The Problem of Definition

The fundamental problem of terminology derives from the fact that it concerns a process resulting in the formation of new communities, and that these communities used a term for themselves that had already originated in the Middle Ages, but was given a different content in different political and cultural conditions. On the one hand, 'nation' in English included all inhabitants living under one government and ruled by the same laws. The first edition of *Grande encyclopedie* also defined '*la nation*' in similar terms, but later the use of a common language was added to this characterization. On the other hand, 'nation' in German and also in Polish, Czech, and so forth was traditionally primarily associated with language, culture, and also sometimes with a shared past. That is why anglophone researchers find it hard to accept speaking about a fully fledged nation in cases where there is no nation-state (Kemilainen, 1964). It was only during the last two decades that the term 'nations without state' was introduced into the scientific discourse (Guibernau, 2007). Another difficulty comes from the fact that 'nationalism' entered the academic vocabulary quite late: it was a neologism originally used in politics and, therefore, laden with political connotations. Nevertheless, the term is also derived from 'nation,' which means that it becomes related to the linguistic connotations mentioned. It follows that anglophone literature will associate nationalism, one way or other, with a state and/or a struggle toward statehood.

Views on Nation, Nationality, and Nationalism in the Nineteenth Century

The study of nation and national consciousness developed alongside the nation-forming processes at least from the mid-nineteenth century and was influenced by the following circumstances: (1) the previous linguistic tradition; (2) the axiom of 'primordiality,' that is, by the idea that the nation *an sich* had existed since the Middle Ages and that people gradually realized their objective belonging to it; (3) the degree of nation-forming of a given nation: English and French researchers presumed the existence of a nation as a nation-state, while for German, Italian, and 'East-European' writers a nation was not commonplace and they were still looking for a suitable definition. It is not a coincidence that the largest numbers of the studies of nation can be found in the German-speaking territory.

It needs to be added that English and later American authors also looked for a definition of a nonstate community. For the most part, they used the words 'nationality' or 'peoples.'

The large number of studies written up until World War II can be divided into two main streams:

1. Nation was defined by objective, empirically researchable characteristics. These usually included, first of all, cultural and linguistic characteristics in combination with various other features – from political ties to territorial, economic, and 'blood' relations. Nevertheless, already at the beginning of the twentieth century some authors concluded that it was impossible to find a universally applicable combination of characteristics, including all entities considered nations at the time. That is why a differentiation between a state and a cultural nation gained support (Meinecke, 1907). The criterion was whether the community that called itself a nation was a state or not. Another approach was to define nation as a 'community with a shared past,' which originally applied only to the members of the ruling

classes and elites, but which integrated the entire population in the course of historical development since the Middle Ages (Bauer, 1907).
2. Nation was defined subjectively – its members were aware of their belonging to the nation and wanted to belong to it. This concept could be expressed in terms of agitation – as a will to form a nation – or existentially, as a sort of a 'plebiscite' – as a decision to belong to an existing national community (Renan, 1888). Typically, the subjectivist concept of nation originally appeared in essays rather than in empirically researched studies. The dividing line between both concepts is not clear cut. On the one hand, supporters of the objectivist definition realized more and more strongly that a nation could not exist without national consciousness.

On the other hand, the subjectivist definition did not preclude a primordialist (or perennialist) concept of a nation. It is symptomatic that national consciousness, or 'nationalism,' became a tool of scholarly analysis as late as in the period between the two World Wars. The pioneer of the study of nationalism, Carlton J. Hayes (1926), presumed that it was necessary to define the object of nationalism, and attempted to define both nation and nationality through objective features.

The Definition of Nation and Nationalism in the Second Half of the Twentieth Century

The sad experience with nationalism during World War II for Europe affected the approaches of historians and social scientists to the study of nation. The political acuteness of this study increased and also with it the political commitment of the authors.

Although opinions continued to vary, most researchers agreed on a number of points in setting priorities in research and in discarding insupportable views:

1. An overwhelming majority of researchers more or less distanced themselves from the view that nation is a timeless category and a blood-related community.
2. Agreement was also reached concerning the impossibility of defining nation only through cultural and linguistic characteristics.
3. Nation was usually accepted as a distinct community only if evidence was available that the members of the community (or at least the prevailing majority of them) considered themselves a nation.
4. Hence the growing emphasis on the study of nationalism as a subjective manifestation or as a precondition for the objective existence of a nation.

Nevertheless, conservative historians perpetuated for a while the traditional idea that a modern nation was a continuation of a medieval nation. After all, studies of national (or proto-national) identities in the Middle Ages and the Early Modern Age are fairly common in Europe.

In the conditions of political bias against German nazism and Italian fascism, the atmosphere in Europe was not favorable for applications of the term 'nationalism' as a neutral tool for historical analysis as it was developed by Hayes (1931). On the contrary, the numbers and importance of authors who considered nationalism a negative extravagance that needed to be overcome increased. According to authors such as Friedrich Hertz, Edward H. Carr, and later also Elie Kedourie (1960), nationalism was invented by irresponsible educated individuals, spread by equally irresponsible demagogues and politicians, and should be eradicated as a dangerous legacy of the past.

A polarized and modified variant of this concept as promoted by Hans Kohn in his numerous publications became more influential. In his view, two kinds of nationalism were to be distinguished: Western, which was rationalist, constitutional, liberal, democratic, and developed in France and the United Kingdom; and Eastern, which was irrational, mythical, racist, and reactionary. Although this dichotomy (Snyder, 1954) was persuasively criticized many times (Kemilainen, 1964; Billig, 1997; Schopflin, 2000), it had a number of adherents.

Most historians and social scientists sought acceptable ways of defining nation as an objectively existing social group during the postwar decades. The approach that it was possible to develop an authoritative set of features every nation had to have survived only as the official (although not Stalinist) doctrine of Soviet research. On the other hand, a number of authors were trying to find a more free definition by combining several kinds of relations. Among these relations, Boyd Shafer (1955) distinguished 'illusions,' such as economic needs, language, and shared history; and objective relations, such as shared government, shared cultural institutions, and social institutions. The sociologist Pitrim Sorokin (1947) saw nation as a 'multibound group' formed by a set of individuals "linked by two or more unibound ties." These could be a territory, a language, a religion, and/or physical conditions. A similar view among sociologists is held by Smith (1991), who characterized nation as a population set sharing the same myths, same historical territory, mass culture, and economy. Another variant of this perspective was a concept of nation as a social group bound by a changing combination of several kinds of historically strengthened, mutually substitutable relations, while civic equality of all members of the group and the consciousness of their shared history were necessary and nonsubstitutable ties (Hroch, 1985).

The problems with finding a common, generally acceptable definition of nation also led to giving up such a definition and favoring the subjective definition of nation: "a nation exists when a significant number of people in a community consider themselves to form a nation" (Seton-Watson, 1977). This change was often associated with the 'discovery' of Renan's concept of nation. The result was an increased frequency of use of the term 'nationalism.' The object of this nationalism was often not defined, or it was characterized as a super-personal entity toward which a nationalist individual feels unconditional loyalty (Lemberg, 1964). This view gradually radicalized: nationalism began to be considered a given reality, while nation was regarded a construct, a myth, or an invention. The theoretical authority became Benedict Anderson (1983) – through no initiative of his own. He called nations 'imagined communities,' by which he meant that a nation as a group could only exist if its members were able to imagine that they belonged to a community of people,

of whom the majority they did not know, and would never know. This view, however, can also be interpreted to mean that nation is just an illusion and an invention and therefore the necessity of its formation can be doubted. The constructivist concepts of nation do not solve the problem of definition, they merely move it to another perspective: they also have to explain the term 'nationalism' in its historical context.

Equally as in the case of nation, there is not a consensus among researchers on the term 'nationalism' either. Quite the contrary, the terminological confusion is augmented by the haphazard use of the term by researchers and without attempts at definition.

However, we can also find important exceptions. John Breuilly (1982) defines nationalism as a politics based on the premise that a nation exists, and which identifies itself with this nation. It demands political autonomy for the nation, usually in the form of a state. Gellner's authoritative definition of nationalism as an effort to obtain the attributes of a state for one's own ethnic entity appears around the same time. Later, Gellner substantially modified his definition: "Nationalism is a political principle which maintains that similarity of culture is the basic social bond" (Gellner, 1997). Recently, some authors propose to understand nationalism as a "discoursive formation" (Calhoun, 2007) or "the way of seeing the world" (Delanty, 2002). This particular form of discourse does not mean a denial of reality (Ozkirimli, str. 2010).

Attention will now be paid to those authors who considered nation as objectively existing, or essential. Karl W. Deutsch (1953) made the first significant attempt at a new approach. He defined nation as "a community of complementary habits of communication." This communication community then forms a basis for a shared national culture and also nationalism. This approach was later more precisely defined as a group of people capable of better mutual than outward communication and cooperation, and which is politically organized and autonomous. Members of the nation then associate community consciousness with certain values and with culture. Thus a foundation was created for the development of nationalism. Another step in this direction is the definition of nation as a "social formation" that is "integrated through the means and relations of communication, production, organization, and exchange" (James, 1996). It needs to be mentioned that the majority of these authors did not know that they were drawing on a concept of Bauer (1907).

The view that nation is primarily defined by statehood is widespread mainly among anglophone authors. J. Breuilly, Stein Rokkan, and Charles Tilly should be mentioned, and also Louis Snyder and Anthony Giddens, who maintain that a nation only exists "when a state has a unified administrative reach over the territory over which its sovereignty is claimed" (Giddens, 1987). Similarly, Eric Hobsbawm concludes that nation is "a social entity only insofar as it relates to a certain kind of modern territorial state" (Hobsbawm, 1989). In these schools of thought, nationalism was closely connected with the state.

Defining nation by statehood runs against an important empirical fact that communities that have had a long way to go to statehood, and sometimes have not even sought it, call themselves nations. Especially in English there is a problem with finding an adequate term for this case.

From the opposite side, cultural activities and traditions are recently again regarded as a factor of central importance defining the modern nation (Leerssen, 2006).

Debate over the Evaluation of Nationalism

As mentioned in section The Definition of Nation and Nationalism in the Second Half of the Twentieth Century, the term 'nationalism' had been a political term until the inter-war period. It was used in both negative and positive senses, referring either to a negative and an antisocial attitude (especially in the political language of the socialist movement) or to a commendable and noble love for one's nation (in the political language of some right-wing movements).

Some authors writing within the Marxist tradition associated nationalism with negative social phenomena. E. Hobsbawm and, less distinctly, B. Anderson are examples of this perspective. It is also true, however, that this same tradition made the important attempt to characterize the 'Janus-face' of nationalism as a phenomenon that could have a negative and oppressive impact on the one hand, and a positive impact as a liberating force in the struggle against national or colonial oppression on the other (Nairn, 1981).

The distinction between the two kinds of nationalism is typical for a large number of researchers, and it is foreshadowed by Hans Kohn's West–East dichotomy mentioned earlier. The distinction between positive and negative nationalisms according to the country or the national context was also used later (Greenfeld, 1992).

Another dichotomy is a distinction between nationalisms according to time periods. In 1956, the influential German historian Theodor Schieder (1991) evaluated nineteenth-century nationalism as a progressive and creative factor, while he criticized the manifestations of the destructive side of nationalism, especially in the first half of the twentieth century. This distinction was later repeated by other authors. Ironically, the official Soviet scholarship also recognized two similar phases, although it did not explicitly use the term 'nationalism.'

A majority of contemporary authors recognize the double face of nationalism in history, but without giving geopolitical meaning. For example, Louis Snyder (1976) considered nationalism as moral, as well as immoral, human as well as inhuman. According to these criteria, it could be evaluated as positive in some cases and as negative in others. He saw the main danger of nationalism in its association with collectivism against individualism. The French philosopher Etienne Balibar and Immanuel Wallerstein (1991) sees the good side of nationalism in that it contributes to the development of state and a community of citizens in general, it derives from the love of people, and it is tolerant. In contrast, the bad side of nationalism is in its expansiveness, hatred, and intolerance. It is symptomatic that the positive potential of nationalism is mostly appreciated by non-Anglo-American authors: apart from the French author mentioned, also the Catalunian historian Josep Llobera (1994) and the Israeli historian Hedva Ben-Israel can be mentioned among many other authors. Liah Greenfeld (2006) finds that nationalism became an important driving force of modernization.

Another group of authors considers the broad meaning of the term 'nationalism' to be a source of imprecisions and

misunderstandings, and recommends the use of the term only to refer to national egoism, preference of one's own nation over others, and placing one's own national interest over the interests of an individual (P. Sugar, L. Doob, O. Dann, W. Norman). Some recommended the use of other terms, such as patriotism (Doob, 1964; Samuel, 1989; Vincent, 2002), love for one's country, national consciousness, and national feelings for the positive manifestations of national identity. Another variant is the recommendation to preserve nationalism as the neutral term and find other terms, such as ethnocentrism (L. Le Vine, D. Cambell), ethnonationalism, xenophobia, or chauvinism for the negative manifestations. A real terminological potential can come from those researchers who take the historical – that is, developmental – perspective. They proceed from the fact that attitudes called nationalism developed from certain previous, developmentally 'lower' attitudes, perceptions, and relations, which are sometimes called identities, at other times loyalty or primordial sentiments. The term 'loyalty' is rarely used in historic research, but it belongs to the terminology of cultural anthropology. It is characterized as "a relation of an individual toward pre-existing given groups, phenomena values – in the social reality in which the individual lives" (Geertz, 1973).

The term 'national identity' now belongs to the common terminology of a number of historical analyses. It is used most consistently by Anthony Smith, who maintains that nationalism needs to be studied as a certain consequence, or as another phase in the development of national identity. At the same time, the consciousness of each individual is determined by multiple identities, which are more or less interrelated. Unlike the term 'nationalism,' the term 'national identity' is not laden or obscured with superficial journalism in the vocabulary of historic analysis. A number of contemporary scholars and projects promote using both terms in different contexts (Guibernau).

The Swedish historian Sven Tagil (1984) suggests a distinction between identity, referring to the simple consciousness of belonging to a group, and identification, referring to the active and committed participation in the work for the nation.

The debate over definitions and evaluation should not be seen as mere academic disputes or noncommittal intellectual exercises. The debate is not self-serving; it is a discussion over whether and how a particular term or concept is suitable for explaining the fact that after 200 years of dramatic and controversial development in Europe, in most cases, the nation-forming process almost everywhere resulted in monoethnic nation-states. Nevertheless, neither national identity nor nationalism disappeared.

Why Nation and Nationalism? Attempts at a Historical Explanation

Every survey of views on the genesis of nations and nationalism is confronted with the contradiction between those who consider nation an invention or a construct – and therefore the product of nationalism – and those who see nation as a result of objective nation-forming processes. Judging from the verbal expressions, the conflict is irreconcilable. However, is that really so, or is the conflict not so fundamental – as Paul James (1996) argues? The work of Ernest Gellner illustrates the productivity of the approach that tries to see reality behind words and aphoristic statements. His apodictic statement about nationalism creating nations is often cited and made absolute by 'modernists.' Few of them realized that Gellner's definition only moved the causal explanation to a different level: the point was to explain why nationalism had gained such a response. At this level, Gellner works mostly with objective social and cultural factors. Similarly, it clearly follows from the statements of Benedict Anderson that nations as 'imagined communities' could only be formed, thanks to particular objective social preconditions. Therefore, a causal interpretation does not necessarily have to dramatically contrast the nation-forming process with nationalism.

Trying to find an easier orientation, Anthony Smith (1998) distinguished several categories of historical explanations of nationalism. Perennialist and primordialist approaches explain the nation building in terms of 'longue durée' and of primordial ties and attitudes (Bergh, Geerts, Fishman, Connor, Hastings). The broad diapason of modernist authors explained nationalism in the context of all kinds of modernization processes, in some cases with stronger emphasis on constructivism, sometimes with elements of perennialism (Anderson, Hobsbawm, Breuilly, Tilly, Nairn, Gellner, Hroch). Between these two main streams Smith positioned his own theory and gave it the name of ethnosymbolism (Armstrong, Hutchinson). Ethnic identities were reinterpreted and used as symbols mobilizing national feelings. Smith considers the postmodernists – who try to find fully new dimensions, partially based on modernist paradigms, partially deconstructing them (Brubaker, Chaterjee, Billig, Ozkirimli) – as more marginal.

The flood of theories of nationalism seems quite justly confusing at first sight, but a closer examination will reveal that most accounts attempting historical explanations of nationalism repeat the same basic relations and factors, although using different vocabulary and concepts. The differences between the authors are then mostly in the emphasis on a particular kind of relation. This is not the case of those who belong to the postmodernist stream, and who are resigned to generalizing explanations of nationalism.

This article will therefore not deal with singular authors but rather it will characterize their evaluation of the relevance of the particular relations and contexts: (1) historical background; (2) ethnic and cultural roots and, within these, also denominational relations; (3) the process of modernization, that is, particularly industrialization – and the ensuing changes of social structure, social communication, and the unevenness of the modernization process; (4) conflicts of interests; and (5) psychological relations.

Historical Preconditions or the Legacy of the Past

The view that nation-forming was an inevitable result of the historical conditions of the past centuries is now considered a traditionalist residue. Despite that, historians as well as social scientists, Anthony Smith the most important among them, still consider the past to be an important component of the causal interpretation of the nation-forming process and nationalism. They differ in the strength of the influence they

ascribe to history and, particularly, in the analytical perspective. To put it simply, the importance of history is seen from two perspectives: from the perspective of institutions or other objectively operating results of the past development, and from the perspective of 'collective memory' or the construct of national history.

In the former the issue is how institutions, relations, and stereotypes surviving from the past influenced nation-forming: it refers to the state, legislation, and also estates, judiciary, borders, internal administration, the extent of centralism, and other concepts. The notion that the right to the recognition of national existence is conditioned by the existence of a national state from the Middle Ages gave rise to the nineteenth-century distinction between historical and nonhistorical nations, that is, nations with or without their own (political) history. Although this distinction is no longer considered relevant, a number of authors still work implicitly with the idea that some nations (such as the French, Dutch, and Portuguese) are a given, natural, and organic part of the state system, while others formed somewhat by accident (the Estonians, Slovenes, Bulgarians, and many others). Authors (for example, Shafer, Breuilly, Hobsbawm, Rokkan, Llobera, Tilly, and Barth) who define nation by statehood or understand nationalism as a struggle for statehood, usually assign an important role to political or state history.

A particular problem in analyzing the role of history is that people expressed views and stereotypes that many researchers would today consider nationalist – that is, manifestations of national consciousness – already in the Middle Ages and especially in the Early Modern Period – a long time before the modern nation-forming processes. Modern historians agree that the pre-Modern manifestations of national consciousness did not include the entire community but only the privileged classes – the nobility and also sometimes the higher burgher categories (Hagen Schulze, Norbert Elias, and others). Bauer was already aware of this in his periodization of national development.

'Collective memory' is the other perspective on the effects of the past on nation-forming. Authors working within discourse analysis particularly emphasize that the strength of past statehood is not important, but the way the past was understood, interpreted, and worked with – and therefore also manipulated in the national interest. Hobsbawm's phrase "invented tradition" is usually quoted in this context, and it usually refers to skepticism toward any real historical continuity. At the same time, it is unthinkable to invent the past without any real evidence. On the other hand, recent research confirmed how important it is to study the creating of the image, the construct of national history under the conditions of nation-forming (Stephan Berger and Chris Lorenz, 2008).

Ethnic Roots of Nationalism

It is understandable that most authors who associate nation and nationalism with state do not ascribe much importance to the ethnic and cultural component of the nation-forming process. Some even consider ethnic consciousness neutral, and not automatically a source of nationalism.

On the other hand, a number of authors consider ethnic identities and cultural particulars an important, if not a key precondition of development toward a modern nation. Anthony Smith (1991, 1986) paid the greatest attention to this relation. He differentiated between the degrees of ethnic identity and considered that an ethnic group could also develop its collective memory. Ethnic groups could also enter into conflictual relations, which in many aspects forestalled national conflicts (Horowitz, 1985). A number of other authors considered ethnic roots of national existence important, despite their differences in terminology: sometimes they spoke of ethnonationalism, sometimes of nationality, and at other times of primordiality or primordial ethnicity.

Unlike the general role of ethnicity, religion is only mentioned in concrete cases (the Balkans, Ireland), and it is not listed among the necessary preconditions of the nation-forming processes. Nevertheless, several authors acknowledge the indirect role of religion as a modernizing factor in education and communication, particularly as an agent of reformation and counterreformation (Anderson, 1983; Armstrong, 1982 and others). The significance of overcoming religiosity with the rise of secularism is also acknowledged. At the same time, some authors see nationalism as a 'national,' secularized religion.

Nation and Nationalism as Manifestations or Consequences of Modernization

The modern nation-forming doubtlessly occurred during the period of civil revolutions, industrializations, and the beginnings of the free market. That is, during the period called modernization by some, overcoming of traditional society by others, and the transition from feudal to capitalist society by other authors. Most authors (unlike, for example, Kohn) consider this simultaneous occurrence more than a coincidence, but they construct the causal relations in different contexts. Already in 1953, Deutsch saw the, industrial revolution and the onset of the free market as crucial for the spread of nationalism. Later, he considered nationalism a response of people on the one hand to the possibilities of improving their status thanks to social mobility, and on the other hand to the loss of ties to the traditional lordships and settlements. Gellner's thesis (1983) about industrialization as the fundamental impulse for the birth of nationalism cannot therefore be seen as original. Gellner, however, does not conceive of industrialization in the literal sense referred to by historians, that is, as the introduction of the industrial mode of production. Rather, he means market economy and social mobility in general as factors opening the way for the principles of equality of citizens and their new role in the transformation of culture. Michael Mann (1988) and other authors, such as Etienne Balibar and Immanuel Wallerstein (1991), work with a similar, although more differentiated, thesis. Carolyne M. Vogler (1985) also shares this perspective when she maintains that the "disjunction between economics and politics" occurred, and that significantly contributed to the dissolution of multinational states and the creation of nation-states. In contrast to the thesis of the role of industrialization, other authors emphasize general modernization changes ensuing from the progressing liberation of the market and people (Hroch, 1985; Llobera, 1994). The emergence of the new forms of enterprise (that is, capitalist enterprise) and the related social mobility are specifically reflected in increasing

social communication, that is, a system of an increasing amount of information being exchanged among an increasing number of people. As mentioned, Karl W. Deutsch ascribed the key importance to this circumstance on the formation of nation and nationalism, but his one-sided emphasis on communication was not generally accepted. His views were nevertheless confirmed within another terminological framework: the thesis about the crucial role of education in the people's ability to accept the notion of a nation as an abstract community became the central argument of Anderson. It was already advocated earlier by Gale Stokes (1974), who proposed that the acceptance of such a notion depended not only on elementary literacy, but also on schooling until the age when a child developed the ability of abstract thinking. The German sociologist Berndt Giesen (1991) connected both of these perspectives: in the conditions of the new type of communication between addressees who did not know each other, a new style of communication and new coding was necessary. The idea of nation became such a code for encoding the new living conditions of modern society.

Numerous researchers argue that the spread of nationalism was boosted by the deepening of the unevenness of development – another consequence of modernization and industrialization. A specific form of unevenness was a 'cultural division of labor between the core and the periphery,' which resulted in the inferior social role of the periphery. This led to the 'internal colonialism' as a breeding ground of national and regional movements opposing the 'center' (Hechter, 1975). Mann (1988) and Nairn (1981) also considered uneven development and the associated sentiments of oppression, important factors of nation-forming processes. The view of the nation-mobilizing role of unevenness ('backwardness') has been criticized frequently and its general validity has been rejected.

Nationally Relevant Conflicts of Interests

This brings the discussion to the factor that – again veiled by the various terms – plays an important role for perhaps still the majority of approaches seeking the explanation of nation-forming and also of the spread of nationalism in objective social changes. The thesis of internal colonialism alone suggested that the conflict between the falling-behind periphery and the center could be expressed in the categories of national interest. In other words, uneven development could be counted among nationally relevant conflicts.

Some authors accentuated the role of international conflicts and above all of wars as a decisive basis of nationalism and national mobilization (Langewiesche, Laitin). There is no doubt that in some parts of Europe – above all in southeast – wars accompanied all cases of nation formation. On the other side, wars used to be rather a consequence and accelerator of militant nationalism instead of being its origin (Hogan, 2009).

All this range of conflicts from wars to socially and status-motivated tensions can be seen as conflicts of interest. This fact makes any generalization difficult, but it also allows for different interpretations. The most frequently listed conflict in the explanations of nationalism is the conflict ensuing from uneven development.

A social conflict between groups or classes that, at the same time, belong to different ethnicities is theorized relatively seldom in contemporary research (Miroslav Hroch, Paul James, Tom Nairn, Eric Hobsbawm), as is the idea of the struggle against an old society in the national interest (Boyd Shafer).

Nationalism as a Result of Psychological, Cultural, and Emotional Manipulation

Most researchers working on the explanations of nationalism also look for its sources in the realm of psychology and emotions. The individual models, however, differ significantly according to which aspect of the human psyche they consider important. Insecurity of a human individual and the need to belong to a group and to identify with it are some of the most frequently quoted aspects. The insecurity is then seen as being caused by perceived (or real) endangerment, while the source of endangerment can be either external danger or internal insecurity resulting from the perception of uprootedness, dissolution of old securities, old faith, and so forth (Miroslav Hroch, Gale Stokes, Anthony Smith, Bernd Giesen, Ernest Gellner). Nationalism is sometimes considered a sick, pathological reaction to such perceived endangerment (Committee on International Relations, 1987), and at other times a response to the inferiority complex (Lemberg, 1964). Anderson speaks of the need to overcome the fear of an individual death by identifying with an immortal nation.

Following partially from Geertz's primordial ties, some researchers tried to apply biological research on animal behavior to nationalism, and explain nationalist attitudes as the 'territorial imperative' (Snyder, 1975). Nevertheless, this approach has remained marginal in the overall context.

'All the stronger' has recently become the effort to explain nationalism as a cultural construct deriving from the activities aiming at the emotional mobilization of human psyche. Thus national rituals are becoming a subject of intense research (Mosse, 1973), as well as symbols, celebrations in the name of nation (E. Francois, Elgenius, 2011), and pilgrimages to places commemorating the national past (Nora, 1986) – in short, activities deliberately aimed at the emotional element of the human psyche. It includes also manipulations through state institutions, media, movies – factors that are regarded as decisive of nationalist mobilization in the eyes of constructivists and postmodernists.

Overall, differences in the explanations of nation formation are not as fundamental as it may appear on the surface from the different terminology and the verbal radicalism of some authors. The understandable efforts for originality and impressive contribution are often a facade of new expressions repeating older conclusions and findings.

Most of the studies on the historical origins of nationalism are flawed in that they ignore the fact that the process of nation-forming was present in two basic types in Europe: the first started with nation-states that had existed since the Middle Ages and began to transform into modern nations at the end of the eighteenth century or later. The point of departure of the second type were nondominant ethnic groups that inhabited the territories of large multiethnic empires, did not have ruling elites, had their own cultural traditions in a codified language, and had either a disrupted or no tradition of statehood. That is why it is important to distinguish between nationalism (whether considered as a part of national identity or merely as

its nationally egoistic variant) developed in the conditions of nation-states and the kind of nationalism known from national movements. The latter type again differs depending on whether it developed under conditions of phase of national agitation (phase B) or a mass national movement (phase C). In any case, nationalism should never be viewed as a compact theory or ideology comparable to liberalism, clericalism, or socialism. It has always been a mixture of variously structured stereotypes that, in the environment of forming a fully fledged nation, had the ability to attach itself to any political ideology and live with it in a symbiotic or parasitic relationship. Abstract

The sociology of nationalism is a fairly new field. Even so, several theoretical approaches to the study of nationalism have emerged: functionalism, modernization theory, neo-Marxism, comparative–historical sociology, social constructionist theories, and rational choice theory. Despite theoretical disagreements about the origins and evolution of nationalism, a degree of consensus has developed: the rise of the nation was intertwined with the emergence of the absolutist state, the idea of popular sovereignty, industrialization, the expansion of cultural communication, and uneven development. The intimate relation between modernity and nationalism contradicts liberal and Marxist expectations of a unified world.

The study of nationalism is a fairly recent development in sociology, a discipline which took for granted the nation-state as the territorial framework of its main subject of investigation – modern societies. Nevertheless, several sociological approaches to the study of nationalism can be distinguished: structural functionalism, modernization theory, neo-Marxism, rational choice theory, and a variety of comparative–historical and social constructionist approaches.

One recurrent theme in sociological debates about nationalism concerns the nature of the relation (historical and conceptual) among several interrelated phenomena: ethnic group, nation, and nationalism. Each one of these phenomena has been seen either as an historical antecedent of the others or somehow accorded priority. Thus, while one of the most influential theorists argues that 'nationalism created nations' (Gellner), another sees nationalism as a 'subjective reflection' of the group reality of the nation on the level of social consciousness (Hroch). In addition, whereas some emphasize the 'ethnic origins of nations' (Smith), others argue that 'ethnic nationalism' is a later-day ideological development (Greenfeld). A second line of sociological debate has separated modernization theorists and neo-Marxists who explain the emergence of nationalism by reference to economic factors or the functional requirements of industrial society, and historical sociologists who question this view on a variety of grounds. An important obstacle to sociology in this field is imposed by the subject itself: as the most salient form of particularism in the modern world, nationalism defies easy generalization.

Nationalism and Classical Sociology

Nationalism was not a central concern in classical sociology. This curious lacuna must be understood in light of the history of a new discipline preoccupied with demarcating its own field of study – society as a reality *sui generis* (Durkheim). A second reason might be sought in the intellectual bias of sociology itself: political phenomena were seen as derivative of more fundamental social realities. Finally, sociological interest was consumed by the dramatic transformations caused by industrialism and capitalism. As a result, concentration on the problems of industrial society overshadowed the concern with its overall territorial framework – the modern nation-state. The rise of imperialism and mass politics at the turn of the century changed this equation.

Max Weber

Weber's views on the nation must be understood in this historical context (Weber, 1978). For him, the unprecedented fusion of culture and politics in the modern world offers the main clue for understanding the nation: its *differentia specifica* as a social group lies in the striving for territorial political power on the basis of a shared culture. This symbiosis of culture and power in the nation-state resulted from a twofold dependency: if the state's legitimacy increasingly depended on nationalist appeals in the age of mass politics, the nation needed the state for the protection of its unique culture. By combining the status concerns of intellectual strata as the bearers of national culture with the Realpolitik ambitions of political elites, nationalism provided the state with a new source of legitimacy, greatly increasing its mobilization potential. The sacralization of the state as the guardian of cultural values, in turn, inevitably transformed national conflicts, both within and between states, into 'a struggle of life and death.'

Second, Weber attempted to explain national solidarity. In contrast to ethnic groups whose members must share a 'subjective belief in common descent,' national solidarity does not depend on a myth of common origin (Switzerland) or objective markers of status differentiation (race, religion, language). Thus, the loyalty of German-speaking Alsatians to France was derived from the historical experience of a revolutionary regime that abolished feudalism. Conversely, the ethnic and linguistic affinity of Serbs and Croats did not obliterate their national differences. Consequently, Weber argued that common historical experiences and shared memories play a decisive role in forging the nation as a community of 'political destiny.'

Weber's third point concerns the mass appeal of nationalism: as the only source of status superiority available to the masses in a secularized world (ethnic or national honor), nationalism cuts across class lines in defiance of socialist expectations. An additional reason for nationalism's appeal to the lower strata has to do with status compensation: In many instances, the denigration of 'inferior' ethnic or racial groups by the lower classes of the dominant group (such as the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.32100-6

emancipated black Americans by the poor whites in the Southern United States) is the very precondition of the latter's status superiority. These observations do not amount to a theory of nationalism; however, Weber's main intuition – that the fusion of culture and power constituted the *differentia specifica* of the nation as a new type of sociological community – became a cornerstone of all later theories of nationalism.

Emile Durkheim and Marcel Mauss

In *The Elementary Forms of Religious Life*, Durkheim notes the similarity between the collective effervescence of religious rituals and revolutionary-patriotic festivals: in the Jacobin phase of the French Revolution, the secular values of Fatherland, Liberty, and Reason became the core values of a revolutionary-patriotic religion whose object of worship was society itself (Durkheim, 1995). For Durkheim, this self-worship of society was another confirmation of his theory of religion. The connection with nationalism as a 'secular faith' remained unexplored in his work. On the other hand, as a committed advocate of secular schools in the Third Republic, Durkheim envisaged an important role for civic patriotism in moral education. During World War 1, Durkheim favorably contrasted this ideal of civic patriotism to expansionist German nationalism, whose excesses he interpreted as a sign of collective *anomie*.

A Durkheimian view of the nation was elaborated further by Mauss (1920). Mauss saw nationalism as a modern phenomenon originating in the doctrine of popular sovereignty espoused by the American and French revolutionaries. Sociologically, nationalism's success as a movement was predicated on the presence of three general factors: (1) a strong central power that successfully broke down traditional affiliations of tribe, clan, and estate; (2) a morally integrated society consisting of citizens who identified with the state and its laws; and (3) economic unity. On the other hand, the belief in a unique racial or civilizational heritage was a retrospective elaboration of nationalists: its importance lay in cementing an already existing social bond on the level of consciousness. For Durkheim and Mauss, the nation was first and foremost a community of citizens; their understanding of ethnic nationalism was limited.

Structural Functionalism

A new sociological interest in nationalism developed as a result of the proliferation of independent states after World War 2. The dominant sociological school of the postwar decades – structural functionalism – viewed nationalism as a by-product of the structural strains caused by industrialization.

Thus, Smelser saw nationalism as a response to the state of collective *anomie* induced by structural differentiation (division of labor, role specialization, etc.). As a secular ideology of industrialization, nationalism overcomes the resistance of traditional structures, mobilizes new constituencies, and gives meaning to the sacrifices required for social change. Conversely, once differentiation proceeds apace, nationalism can take the form of a nativist reaction against the corroding influences of further modernization (Smelser, 1966).

This logic was generalized by Shils, who built on Durkheim's idea about secular nationalism as the functional equivalent of religion: the transition from loosely integrated traditional societies to the modern nation-state is predicated on the gradual penetration of the various social and geographical peripheries (kinship, ethnic, religious, and regional) by the 'charismatic center,' seen as the embodiment of a society's core values (Shils, 1975). By allowing the members of society to partake in the institutionalized charisma of a sacralized political center through the exercise of citizenship rights, the nation-state succeeds in breaking the power of tradition. This sacralization of the secular is of special significance in transitional societies. By transposing the charisma of the tribe or religion onto the nation, the leaders of new states are able to attract mass support and legitimate social change.

Functionalist explanations can be criticized on the following grounds: (1) there is no inevitable correlation between structural differentiation and nationalism; (2) teleology: the end-state is posited by the observer and used to explain the past; (3) the desirability of meeting select functional goals is subject to elite contest; and (4) nationalism is a secular ideology more similar to other modern ideologies than to religion.

Modernization Theory

A significantly modified functionalist modernization approach was developed by Karl Deutsch and Ernst Gellner. The formulations of these two theorists have remained influential to this day.

Karl Deutsch

Deutsch (1966) begins with a distinction between society and culture. Society refers to the division of labor and social stratification; culture, on the other hand, is a set of 'stable, habitual preferences' based on values inculcated through socialization. Societies 'produce, select, and channel goods and services'; culture stores information about the past and recombines it in the present, enabling political authority to function. The technological changes and complex division of labor induced by the industrial revolution resulted in a growing need for expanding channels of cultural communication. Simultaneously, the breakdown of traditional status barriers and exposure to the insecurity of the market raised the aspirations of the socially mobilized masses, already agitated by democratic ideas. These developments favored the emergence of the nation as a horizontal functional group linked by complementary communication channels, typically language (e.g., Czechs versus Germans in Bohemia), but also shared memories or historical experiences (e.g., Switzerland). As *the* ideology of popular sovereignty, nationalism held a special attraction for the socially mobilized masses whose claims to status equality and upward social mobility it helped justify.

Deutsch's theory is empirical and predictive: the complementary character of communication channels can be assessed by social-psychological indicators; rates of social mobilization can be measured by urbanization, mass literacy, newspaper circulation, etc.; and assimilation depends on the extent and content of communication between in and out-groups. The theory runs counter to the standard predictions of Parsonian

structural functionalism: the expansion of communication strengthens nationalism, not universalism.

Ernst Gellner

Gellner (1983) starts with an ideal type of agrarian societies; their central feature is an ideologically buttressed functional division of labor that separates the 'high culture' of a hereditary administrative-military ruling class and universal clerisy from the 'low cultures' of socially isolated and illiterate peasant communities. This status segregation has a cognitive dimension as well: the world is experienced as culturally and ontologically heterogeneous.

A profound change occurs with the modern cognitive revolution. The world is now seen as a coherent whole subject to universal laws expressed in a unitary linguistic idiom. The social correlate of this cognitive revolution is industrialism. If intellectual progress presupposes the perpetual exploration of reality, the idea of unlimited growth demands the constant redrawing of traditional social boundaries and roles in line with the functional requirements of the division of labor. These requirements can be met only by a common linguistic idiom transmitted through standardized education. Literacy in a shared language prepares individuals for new functional roles, increases their mobility prospects, and facilitates communication among strangers in an impersonal world. The emergence of a shared culture favors nationalism as a political principle which holds that the state must rest on the foundation of national culture; the state, in turn, acquires a new source of legitimacy (cf. Weber). Thus, industrialism is a necessary condition of nationalism. Ethnicity is secondary; it is nationalism that invents nations.

Finally, nationalism disseminates through uneven development. In a typical imperial (e.g., Habsburg) situation, an ethnic division of labor is present; the carriers of high culture belong to one ethnic group (or groups), those of low culture to another (or others). The social exclusion of the aspiring intelligentsia of the subordinate group leads it to adopt ethnic nationalism as a strategy of collective mobility (e.g., Czech nationalism). In contrast, 'diaspora nationalism' develops among politically excluded high culture pariah groups (e.g., Jews). The ideal case is a mature industrial society in which elites and masses share a standardized idiom and consider themselves to be conationals in a common state.

Gellner's elegant theory has enjoyed enormous influence. It can be criticized on several grounds: (1) the theory does not specify a causal (group) agent, nationalism is seen as a byproduct of the impersonal process of industrialization; (2) nationalism can precede industrialization (e.g., Balkan nationalism); (3) nations can precede nationalism; and (4) nations are rooted in premodern, ethnic identities (see Section Comparative–Historical Sociology).

Neo-Marxism

The classics of Marxism failed to develop a consistent sociological theory of the nation (Szporluk, 1988). Although partially filled by Austro-Marxism (Bauer, Renner) and the Bolshevik ideologists (Lenin, Stalin), this lacuna was addressed seriously only after World War 2. A strong impetus to the Marxist sociology of nationalism was given by Immanuel Wallerstein's world system theory: in the underdeveloped periphery of the world capitalist system, class struggle (indigenous proletariat and peasantry versus the comprador bourgeoisie) and national conflict (the exploited nation versus the world capitalist metropole) were superimposed upon each other.

Class and Peripheral Nationalism

Hechter (1975) extended the metropole–periphery logic to ethnic conflict in the British Isles. In defiance of functionalist logic, the incorporation of the (Celtic) periphery by the (English) center did not result in the creation of a homogenous national society, but a dynamic of 'internal colonialism' instead. The subordination of the underdeveloped periphery was ensured by its economic dependence on a developed center and a rigid ethnic division of labor that enabled the English to monopolize power and status privileges. The persistence of ascriptive status identities and the superimposition of class and ethnic conflicts run counter to the expectations of modernization theory: instead of integration and consensus, uneven development leads to the resurgence of peripheral nationalism.

Studying the same case, Nairn (1977) came to a different conclusion: peripheral 'neonationalism' could be caused by 'relative overdevelopment' as well. Thus, the resurgence of Scottish neonationalism was the result of the relative economic decline of the English center and new opportunities opened by oil exploitation in the North Sea. A newly awakened Scottish bourgeoisie in search of profit appealed to nationalism in its struggle against a parasitic center. In larger historical perspective, nationalism was a product of the ideological reaction of the awakened intelligentsia of the semiperiphery to uneven development and imperialist exploitation of their countries (not yet nations) by the centers of world capitalism (England and France). The nationalism of the center, in turn, developed in 'dialectical counter-mobilization' against its semiperipheral counterparts.

Class and Nation: The Social Base of Nationalist Movements

The relationship between class and nation is a central concern in Hroch's (1985) study of the developmental phases and social base of nineteenth-century national movements in small European nations. For Hroch, the nation is an 'objective social category' rooted in the memory of a shared ethnic past, dense linguistic and sociocultural ties, and a conception of citizenship. National awareness and nationalism are only a 'subjective reflection' of this reality on the level of consciousness (contrast Gellner).

Hroch distinguished three phases in the development of national movements: in phase A (ethnographic), linguists and folklorists rediscover a shared past; in phase B (agitation), intellectuals promote national awareness among the masses; finally, in phase C, a mass national movement arises. While the social base of nationalist movements varied, especially in phase B (teachers in Slovakia; petty bourgeoisie in Norway), the social mobilization of the bourgeoisie and peasantry was a necessary condition for success in phase C: an independent nation

requires 'a fully developed class structure.' Another necessary condition of nationalist movements was the superimposition of ethnic and class conflicts: only when membership in a small nation appeared as a decisive disadvantage could 'social contradictions' be expressed in national terms. Hroch did not conflate class and nation; however, he did argue that a successful national movement must be based on distinct class interests.

Neo-Marxist approaches can be criticized for (1) an unwarranted reduction of national to class conflicts; (2) limited generalizability (internal colonialism); and (3) an inability to explain the nationalism of the metropole of the world system (England, France).

Comparative–Historical Sociology

Historical sociologists have questioned functionalist and Marxist explanations in two ways: (1) by emphasizing the ethnic or early modern roots of nationalism and (2) by demonstrating that nationalism predates industrialization.

Ethnic Groups and Nations

The first type of argument is developed by Smith (1986), who builds on the pioneering work of Armstrong (1982) on 'nations before nationalism.' Smith rejects the view that nations are based on primordial ties (e.g., race); however, they *are* rooted in premodern *ethnie*. *Ethnie*, in turn, are not based on ascriptive criteria, but on intergenerationally transmitted 'constitutive myths' (ethnic *mythomoteurs*). Typically, such constitutive myths include or imply a collective name, a myth of common descent, a shared historical narrative (legends, epics), belief in a unique culture, association with a territory, and solidarity vis-à-vis out-groups. The transformation from *ethnie* to nations occurred under the impact of the triple revolution of administrative centralization, capitalism, and 'cultural coordination.' Capitalism helped bind social classes into a unified economic community; political centralization, warfare, and cultural coordination (the rise of vernacular languages and mass culture) forged the link between state and nation. Whereas nation-building paths varied in accordance with historical timing, religious identifications, the character of the constitutive myth, and its elite carriers (aristocracy, bourgeoisie, intelligentsia), two broad trajectories emerged as a result of uneven development (1) the early Western path in which the nation was defined as a territorial community of citizens bound by laws and (2) the late 'German' (East-European) route in which *ethnie* served as the basis for statehood. However, Western nations also required a constitutive myth: premodern cultural identities were crucial everywhere, and industrialization was only one factor that helped transform *ethnie* into nations.

Nationalism as Ideology

Another approach is exemplified by Greenfeld (1992): nationalism is an antecedent of industrialization. Greenfeld traces the idea of the nation to a long process of semantic transformation: originally applied to groups of students in medieval universities and the elite of a 'community of opinion,' in sixteenth-century England 'the nation' was extended to include the whole people. This momentous change from the medieval (people = rabble) to the modern *Weltanschauung* (people = elite) was caused by the structural crisis of feudal society. In the first nation, England, the decimation of the aristocracy and the decline of the clergy (War of the Roses; separation from Rome) shattered traditional status barriers, opening channels of social mobility to gentry and educated commoners. The profound status inconsistency felt by members of the elite led them to discover the nation: the view that status inequality was secondary to membership in a community of citizens resolved their identity crisis and legitimized social mobility across status lines. English nationalism culminated in popular sovereignty and an individualistic and civic ideological self-definition: the nation was a composite of individuals, and membership was open to all citizens (likewise the United States).

The diffusion of nationalism was a consequence of England's hegemonic status. Thus, the eighteenth-century French nobility, squeezed between the absolute monarchy and wealthy commoners, imitated its English counterpart and competitor, finding in nationalism a solution for its own identity crisis. However, while membership in the French nation was open to all (as in civic nationalism), the nation came to be seen as expressing a single collective will (*volonté générale*); thus, French nationalism was collectivist and civic. A further semantic transformation occurred in Germany and Russia, where the term was associated with ethnicity – the unique character of a people; nationalism became both collectivist and ethnic. The motor force behind this change was *ressentiment* – the profound existential envy felt by the elites of follower societies toward the 'superior' West; hence the compensatory glorification of the *Volk* with all its authoritarian implications.

Subsequently, Greenfeld (2001) extended this theoretical framework to the relationship between nationalism and economic growth. Instead of Weber's proverbial Protestant ethic, Greenfeld sees nationalism as the main cultural source of 'the spirit of capitalism,' i.e., the modern orientation to sustained economic growth. As an inherently egalitarian ideology, nationalism breaks down the status barriers of traditional societies, opens the doors to social mobility (careers open to talent), elevates 'traditionally disparaged occupations' (e.g., trade), and legitimizes profit-making activity (Greenfeld, 2001: pp. 22–23). In the pioneering case of England and other civic-individualist nationalisms (e.g., the United States), economic achievement was defined as a positive national value because it empowered individuals who constituted the nation. However, even in the case of England, the initial emphasis of economic nationalism was on the common good of the nation as a whole rather than on the relationship between the public good and private interests of constituent members. The idea of a 'natural' *homo oeconomicus* was a later development, predicated on the gradual emancipation of the economic sphere from religion, politics, and status considerations, and its reconstitution as an independently legitimate domain of social action. Subsequently, economic nationalism developed as a reaction to the contagious effect of the English model and in competition with it; in nations like Germany or Japan, economic growth was

harnessed to the political emancipation of the nation from foreign domination and propelled by state action. Where economic achievement, however, was not seen as an important national value (e.g., Russia), nationalism was not conducive to economic growth.

Greenfeld's conclusions are original: (1) democracy emerged from individualist and civic nationalisms; (2) ethnic nationalism is a later ideological elaboration; (3) the historical carrier of nationalism is not the bourgeoisie, but aristocracy or intelligentsia (Germany); (4) both capitalism and democracy could flourish only once the idea of the nation delegitimized traditional status barriers; and (5) nationalism is the main source of 'the spirit of capitalism.'

Greenfeld's theory avoids materialism and teleological functionalism; however, it can be criticized on both theoretical and empirical grounds: (1) the dichotomy between civic (Western: whether individualist or collectivist) and ethnic collectivist (Eastern) nationalisms is far from clear-cut, as Western nations were also based on an ethno-symbolic foundation (Smith, 2009), while cultural nationalism can cut across the civic–ethnic divide (Hutchinson, 1987); (2) early national consciousness should not be equated with a fully developed nationalism: English nationalism developed considerably later than the sixteenth century (Kumar, 2003); (3) cultural determinism: some nations (the United States, England, France) appear destined for democracy, while others seem doomed to authoritarianism (Germany, Russia); and (4) nationalist ideology may be a necessary precondition for legitimizing social mobility across status barriers and enabling capitalist development, but it can hardly explain economic growth.

Nationalism as Cultural Idiom

The continued salience of civic versus ethnic national self-definitions is documented by Brubaker (1992). In France, the republican tradition defined the nation as a territorial 'community of citizens'; membership was not tied to ethnicity. In Germany, a territorially divided nation was defined as a 'community of descent': all (and only) Germans were members. The persistence of these cultural idioms (not instrumental interests) helps explain the difference in immigration policies: the French one became assimilationist and inclusive, the German one ethnic and exclusive.

Social Constructionist Approaches

Nation as Invented Tradition

The socially constructed character of all collective and, *ipso facto*, national identity is emphasized by a variety of contemporary authors. One influential version of the argument is developed by Hobsbawm and Ranger (1983): the nation is largely a product of 'invented tradition.' By 'invented tradition' is meant "a set of practices, normally governed by overtly or tacitly accepted rules and of a ritual or symbolic nature, which seek to inculcate certain values and norms of behavior by repetition, which automatically implies continuity with the past" (Hobsbawm and Ranger, 1983: p. 1). The modern nation is a particularly good example of invented tradition: although the nation-state with its well-demarcated territory and standardized national language is an eminently modern phenomenon, nationalists typically claim it be a 'natural community' rooted in the 'remotest antiquity.' In actual fact, national symbols, flags, languages, and histories are a product of nationalist social engineering, while the connection with the remote past is retrospectively established by nationalist imagination. It follows from this that the main task of the historian and sociologist is to study those symbolic and discursive practices that helped establish the particular nation's idea of itself as a natural community in the first place.

Nation as Imagined Community

A related argument is developed by Anderson (1991) who sees the nation as a new type of limited and sovereign 'imagined community.' The nation is an imagined community because most of its members will never know each other; it is imagined as a limited community because it is externally bounded by other nations; and it is seen sovereign because it is historically rooted in the idea of internal and external freedom (popular rule and national independence). Finally, the nation is imagined as a community, because it is 'always conceived as a deep, horizontal comradeship' (Anderson, 1991: p. 7). The emotional resonance of the nation stems from the fact that it replaces kin and religion as the main locus of individual loyalty and self-sacrifice in the modern era.

According to Anderson, the emergence of the nation as a new type of imagined community was predicated on the presence of certain definite cultural and material conditions: (1) linguistic diversity; (2) the increasing relevance of vernacular languages and literacy after the Protestant Reformation; and (3) "print capitalism" – the production of books, newspapers, and journals for mass cultural consumption. Once set in motion, print capitalism gave an unprecedented stimulus to the development of nationalist discourse, albeit under a variety of historical circumstances that require separate study.

Social constructionists correctly attacked the fallacy of group realism. However, their views can be subjected to the following criticisms: (1) while the nation might be invented, this social construction must be based on a preexisting reality, be it the memory of historical statehood (e.g., Croatia, Poland), ethnicity (e.g., Germany), or a more complex combination of various factors (e.g., Austria); (2) in view of the above, modern national identity might be 'invented' but it is not 'fabricated'; (3) political factors (warfare, state centralization) and elite (or class) interests played an equally important role in the emergence of nationalism as 'print capitalism'; and (4) the notion of 'imagined community' applies to other kinds of communities besides the nation (e.g., class, religious denomination). Such objections provided an impetus for revisions of the social constructionist position.

Nationhood as Institutionalized Form, Practical Category, and Cognitive Scheme

Brubaker (1996) challenged the fallacy of sociological "group realism" from the standpoint of the new sociological institutionalism: instead of treating the nation as a "substantial entity, collectivity, or community" that can be objectively defined, sociologists should study 'nationhood' from the point of view of its political and cultural institutionalization, both within and

among states. Thus, the dramatic collapse of the Soviet Union has to be understood as a consequence of the ethnoterritorial institutionalization of nationhood both on the group (ethnic federalism) and individual (personal identity document) levels. Such institutionalization turned ethnicity into an 'organizing principle of social classification,' constituting the interests of social groups and individuals, serving as a basis for political action, and informing practical conduct in everyday life. Thus, nationalism is not so much 'engendered by nations' as it is induced by particular institutional arrangements.

In a further elaboration, Brubaker (2006) argued that ethnic groups, races, or nations should not be thought of as objective entities but rather as 'ways of perceiving, interpreting, and representing the social world,' i.e., as 'practical categories, situated actions, cultural idioms, cognitive schemes, discursive frames, organizational routines, institutional forms, political projects, and contingent events.' This emphasis on ethnicity and nationhood as cognitive frame, social process, and relational category is designed to prevent sociologists from reifying ethnicity while simultaneously avoiding the reductionist pitfalls of methodological individualism. Cognitive approaches can help explain how ethnicity and nationhood are constructed through actions in everyday life, thus avoiding the traditional preoccupation in social constructionist approaches with elite manipulation of nationalist discourse and symbols.

Nationalism as Discourse, Narrative, and Event: Religion and Nationalism

Gorski (2000) challenges the idea that secular nationalism is a functional substitute for traditional religion by arguing that Dutch national consciousness arose in the early modern era on the basis of a Calvinist-inspired 'Hebraic nationalism.' In the course of subsequent religious conflict and the Dutch revolt against Spain (1555–1609) a full-blown nationalism developed: a sense of the cultural uniqueness of the *Netherlandish* nation (religion, language, custom) blended with political revolt, social mobilization (vernacular literacy), and emerging ideas of popular sovereignty (the state should emanate from the 'people/nation'). An analogous development took place in England, where the commemoration of Protestant martyrs was associated with the idea of England as an 'elect nation.' Both in England and in the Netherlands, however, 'Hebraic nationalism' competed with rival nationalist discourses (e.g., republican, monarchist). The distinction between early modern protonationalism and modern nationalism thus is not as sharp as modernist theorists posit. Consequently, historical sociology should focus on the various 'threads' (historically bound discourses) and 'fibers' (nationalist narratives) from which the whole 'fabric of nationalist discourse is composed.' Nationalism is best defined "as any set of discourses or practices that invoke the nation" (Gorski, 2000: p. 1461).

This view is seconded by Zubrzycki (2006): the originally civic nationalism of Poland's 'republic of nobles' was ethnicized as a result of the nation's territorial dismemberment in the late eighteenth century. Religious subjection, shared language, and the appropriation of religious symbols by romantic nationalist intellectuals resulted in the identification of Polish nationality with Catholicism (Poland as 'the Christ of nations'). Religious self-identification thus became integral to national identity at a later date, and nationalism did not become fully secular as modernist theories posit. Once cemented by recurrent historical experiences (e.g., subjection under Soviet communism), nationalist 'narrative structures' and accompanying symbols (the cross; the Black Madonna of Czestochowa) came to constitute the nation as a 'category of practice.' Even so, the nation remains a 'daily plebiscite' (Renan): the salience, meaning, and use of nationalist discourse (including symbols and rituals) vary across time (political context), while contentious events play an important role in evoking 'collective representations' of the nation. This 'eventful sociology' defines the nation as a "discursive space constituted by a web of representations articulated by various communities of discourse around specific events, and constituted also through the practical uses of symbols commonly understood as 'national'" (Zubrzycki, 2006: p. 216).

Rational Choice Theory

Avoiding grand debates, rational choice theory attacks the fallacy of sociological group realism from the point of view of methodological individualism: how do nationalist movements overcome the free rider problem? A good illustration is Hechter's (1987) analysis of nationalism in Quebec: regional managerial positions served as a selective incentive for the Francophone middle class. Once the spoils of office were distributed, however, nationalist politics abated. Consequently, in addition to offering private goods, nationalist elites must prevent the defection of followers. From these two conditions (selective incentives, internal control), a series of predictive hypotheses emerges. Another illustration is offered by Laitin's explanation of variations in the linguistic assimilation of Russian-speaking minorities in four different post-Soviet republics by the 'linguistic calculus' of individuals faced with the prospect of assimilation: economic returns, the status costs of defecting from the in-group, and the degree of out-group openness emerge as key predictors of the likelihood of assimilation. Thus, cultural choices are shaped by rational calculations about material rewards and social honor (Laitin, 1998).

Rational choice theories of nationalism can be criticized on the following grounds: (1) collective ideologies like nationalism cannot be reduced to the aggregate actions of individuals; (2) value choices are not 'mere' preferences: the intergenerational transmission of myths, collective memories, and narratives shapes the outlook of members of the nation and constrains choice; and (3) nationalist appeals contain a powerful symbolic (irrational) dimension that is critical for explaining the intensity of national feelings and nationalist mobilization.

Conclusion

Despite the fact that nationalism did not stand at the center of sociological interest, especially in the classical epoch of the discipline, sociologists have studied the topic from a variety of perspectives. Even so, a considerable area of agreement has emerged. For one, sociologists agree that the nation is not based on primordial ties; rather its emergence as a community of citizens was related to rise of the modern state (administrative

centralization), the novel idea of popular sovereignty, industrialization, and the expansion of cultural communications (vernacular languages, literacy). Uneven development was crucial for the dissemination of nationalism, whether on account of the ethnic division of labor, the reaction of the exploited periphery, or *ressentiment*. The salience of ethnicity (itself not an ascriptive, but subjective category) was greatest in areas where class and ethnic conflicts were superimposed (e.g., Habsburg empire), the putative nation lacked a state (e.g., Poland), and ideology conceptualized the nation as *Volk* (e.g., Germany). Conversely, ethnicity was secondary in established states (e.g., England), or where shared memories and experiences favored other identifications (e.g., Switzerland). The consolidation of national identity everywhere involved a considerable effort at the invention of tradition. However, the protean character of nationalism as an adaptable and malleable set of ideas, collective representations, symbols, and 'cognitive frames' ensures that the 'making of nations' is a continuous process, albeit one that takes place within the constraints imposed by dominant narratives. The intimate relation between modernity and nationalism defies liberal and Marxist expectations of a unified world; this may well be the most provocative insight of the sociology of nationalism.

These areas of agreement point to considerable progress in the sociology of nationalism. This progress is also manifested in the growing number of areas that sociologists have begun to investigate: religion and nationalism, nationalism and collective violence, nationalism and collective memory, nationalism and gender, the nationalist narrative, nationalism and everyday life, nationalist symbols and rituals, national identity and ideology, dominant and peripheral nationalism, diaspora and homeland nationalism, nationalism and immigration, and nationalism and globalization. Still, many sociologists seem reluctant to fully engage with nationalism; this is understandable, since to an extent all individual nationalisms tell their own stories, and this presents obstacles to generalization. Yet, as Max Weber demonstrated, the uniqueness of a phenomenon neither diminishes its importance nor precludes sociological investigation: a conceptually informed comparative–historical sociology can develop middle-range theories while taking into account the peculiarities of individual instances.

Nations and Nation-States in History

Abstract

The article begins by considering the debate about the existence and significance of nations and nationalism before the rise of the nation-state in the modern period. It then considers the role of nations and nationalism in the formation of nation-states. This begins with Europe, looking at the distinct processes of state reform, national unification, and separatist nationalism in producing different kinds of nation-states. The role of international relations and war is also considered. The following section turns to nation-state formation beyond Europe, especially the waves of new states following the two World Wars and the collapse of the Soviet Union. The article concludes with some reflections on the future of nations and nation-states.

This survey starts by asking whether nations existed before the establishment of nation-states. It then considers the formation of national states before the development of nationalist movements. The next two sections look at nation-state formation in and beyond Europe around 1850 to 1970. A final section considers the place of nations in a world of nation-states.

Nations before Nation-States?

Nationalists answer this question in the affirmative. In the beginning was the nation. As the nation acquired consciousness of itself, there arose explicit demands and movements (nationalism) seeking autonomy, usually a nation-state. The nationalist sequence is therefore nation > nationalism > nation-state.

Nationalist historiography frequently locates the 'nation' in the distant past. Arminius (Hermann) is celebrated by German nationalists for his victory over Roman legions in AD 9. The feudal kingdoms succeeding the Roman Empire are presented as national: the Western Frankish kingdom equals France and the Anglo-Saxon kingdoms equal England. Nationalist etymologies are full of references to the English, French, Germans, Italians, etc.

This view appears plausible for cases like England with a long continuity of institutions bearing the national name. Nationalist historians of subordinate groups in imperial states or of stateless, nonliterate societies have greater difficulties. Political fragmentation also presents problems, even given evidence of cultural identity (e.g., Italy, Germany). There were some premodern societies with sources that seem to claim an ethnic or religious unity between elites and nonelites against foreign rule (e.g., Jewish resistance to Rome). However, powerful premodern states were characterized by divisions between elites of priests, warriors, and officials, usually serving a monarch, and the mass of subjects. Elites referred to ethnicity but this was an aristocratic discourse and subordinated to religious and dynastic values. Subjects were transferred from one ruler to another without reference to their 'nationality.' Indeed, the puzzle would be if elites in highly stratified and undemocratic societies sought to identify with those they ruled.

A more significant argument is that premodern ethnicity is an important condition for modern national identity (Armstrong, 1982; Hastings, 1997; Smith, 1986). Against this is the view that references to ethnic identity do little more than provide modern nationalists with historical material that they can use politically, although that indeed can be important (Breuilly, 2005). There is general agreement that nationalism and the nation-state are modern. However, just *how* modern; what the relationship is between state, nationalism, and nation-state; and why the nation-state has become the dominant political unit of modern times are matters of debate.

Nation-States before Nationalism

In Europe, around 1500, there was little idea that the political order was only legitimate if national (however, see Hirschi, 2012). Germany and Italy were fragmented. By 1600, some voices called for national unity in Italy and the United Provinces against foreign domination. Nevertheless, political loyalty was overwhelmingly to existing states with their republican (city-state), confessional, and dynastic legitimations.

Dynastic empires ruled over different ethnic groups. Henry VIII described his kingdom as an 'empire,' ruling Wales and Ireland, and claiming parts of France. The Habsburg dynasty ruled Austria, much of Southeastern Europe, Spain, Belgium, the Netherlands, and South America. The Valois and Bourbon dynasties claimed territories beyond those of contemporary France, itself inhabited by different language groups. By the seventeenth century, the Romanovs were extending their rule beyond the core of Russia, west and south into Slav regions and north and east into Asiatic ones. Opposition came not from 'Slavs' or 'Asians,' but from other dynasties, e.g., the elective Kings of Poland (Saxons). The core of the Hohenzollern dynasty, Brandenburg-Prussia, included Polish speakers. The Ottoman Empire ruled Slav populations, Muslims, and Christian.

The national idea was unimportant. Historians write of long-term 'winners' emerging as the core of later nation-states (England, France, Spain, Prussia, Russia, and Piedmont). However, these had no stronger, more consciously 'national' characteristics than long-term 'losers' like Poland–Lithuania,

Burgundy, Brittany, Habsburg Austria, the Ottoman Empire, city-states, and small princedoms (Davies, 2011). Beyond Europe, there was little one could call a national state (arguable exceptions are Ethiopia and Japan). Often, there was no distinct state but systems of lineal rule described as stateless or tribal. Again, dynastic empires ruled over many ethnic groups, e.g., in China and India.

Only after 1500 was the national idea used to legitimize states and political movements. In England, the construction of a common legal and administrative system from the late Anglo-Saxon period, the growing importance of Parliament, island situation, increased emphasis on the vernacular language, an economy and polity increasingly dominated by the growth of London, and the national emphasis of the Protestant Reformation combined to make the national idea salient. Shakespeare in *Henry V* (1599) delineates Irish, Welsh, and Scottish stereotypes, although all support the king (Shakespeare only constructed English stereotypes at an elite level in contrast to other Europeans, e.g., the suitors for Portia's hand in *The Merchant of Venice*). The enemy was France, but hostile stereotypes were confined to the elite, not the people. The play includes Henry wooing a French princess; his marriage and military campaigns are designed to maintain power in France. Ethnic and national ideas are prominent but subordinated to the monarchical principle. If England was the most 'advanced' case, this suggests the marginality of the idea elsewhere in 1600 (on stereotypes, Leerssen, 2006).

Four processes increased the importance of national arguments: confessional conflict, absolutism, new political opposition, and intensification of interstate conflict. All developed alongside an extension of European influence beyond Europe and the growth of a commercial economy that undermined privilege and brought into politics 'middling sorts' of people – financiers, lawyers, merchants, commercial farmers, and manufacturers.

The Reformation challenged the dominance of Papacy, Catholic clergy, and the use of Latin. Translations and mass circulation of the *Bible* into vernacular languages along with efforts to extend literacy, because individuals must know the word of God and take responsibility for their souls rather than leaving it to priests, gave a national flavor to Protestantism. Luther challenged the Italian Pope as a German, and Henry VIII as an Englishman. In Spain and France, the monarchy took control over the Catholic Church, creating a 'national' church. Popular religious movements share affinities with later nationalist movements. Nevertheless, religion mattered more than nationality, and only when combined, usually under princely control, did national language figure prominently in politics.

Princes extended their powers by sale of office, appointment of extraordinary commissioners, legal codification, subordination of church, greater taxation, and the establishment of standing armies, processes summarized as 'absolutism.' There was nothing intrinsically 'national' in this, but where the core territory could be regarded as national, e.g., Spain, England, and France, this was justified by national arguments (Anderson, 1974).

This affected political opposition. By 1620, the English Parliament presented itself as a defender of national freedoms. *Parlements* and provincial estates in eighteenth-century France depicted the crown as despotic and themselves as guardians of national liberties. These arguments could escape beyond elite control. In England in the 1640s, national claims were extended to the 'poorest he' by radicals in the Putney Debates. In France, radical values were projected upon the Estates-General summoned in 1789, soon converted into the 'National Assembly.' Monarchy was redefined as at best the servant of the nation, at worst its enemy (Breuilly, 1993: Chapter 3).

Conflict between states had national consequences. Wars in late seventeenth- and eighteenth-century Europe were 'cabinet wars,' the War of Spanish Succession, Austrian Succession, etc. However, they had a global dimension. The central struggle was between France and Britain for world hegemony, using other states as proxies. The struggle extended to India and North America (Schumann and Schweizer, 2008). The wars mobilized the expanding resources of commercializing, imperial economies. They engaged the attentions of an ever-larger part of the population. Commercial growth was associated with the rise of a print culture. In England, the electorate increased in size. In France, the crown and its opponents resorted to pamphleteering, appealing to 'public opinion,' and presenting political conflicts in national terms.

These national arguments accepted the territory of the state but questioned its legitimacy.

> The Nation is essentially the source of all sovereignty; nor can any individual or any body of men, be entitled to any authority which is not expressly derived from it.
>
> (Article III of the French Declaration of the Rights of Man and Citizen, 1789).

The nation was the body of citizens within the existing state. For radicals this meant all adult males. If ideology was logical, this would mean that the national idea was purely political. However, cultural elements were soon introduced.

The idea of a state occupying a national territory associates national virtues with the state. As the French revolutionary state plunged into crisis, it took up these associations. The ethnic and linguistic characteristics of the regions that rebelled against the Jacobins, let alone of opposing states, were linked to counter-revolution:

> We have observed that the dialects called Bas-Breton, the Basque dialect, and the German and Italian languages have perpetuated the reign of fanaticism and superstition, revered the domination of priests and aristocrats, and favoured the enemies of France.
>
> Speech in the National Assembly by Barère, quoted in Carlton J. Hayes, The Historical Evolution of Nationalism.
>
> (New York, 1931: p. 65)

Opponents of the Jacobins presented the 'true' France as Catholic and monarchical in which the historic provinces and the estates enjoyed autonomies and privileges. Edmund Burke depicted nations as carriers of traditions that bound together generations and inhibited the arbitrary and destructive use of reason to alter institutions.

This greater use of national arguments was reinforced by the making of sharp distinctions between 'state' and 'society' and

between state boundaries. Such changes became apparent during the Napoleonic wars. The French revolution abolished distinctions of privilege in France and exported this principle beyond France. This did not herald an era of freedom and equality. New governments were often more autocratic than their predecessors and political rights were restricted to a small minority. Nevertheless, equality before the law was introduced and a clear distinction was made between the state as public power and society as private. When governments appealed for support, they appealed to that 'whole' society rather than to privileged minorities.

Opponents of Napoleon noted that he could tap popular enthusiasm and linked this to new freedoms achieved in France. Reformers advocated the removal of privilege and the extension of political rights to strengthen support for the state. In politically fragmented regions, some invoked the 'nation' as a unifying and mobilizing principle. The nation was presented as a cultural entity from which should rise nation-states, unlike France where the state created national unity. The idea was weak at first, although stronger in Germany than in Italy, probably because in Germany there were national traditions such as the Holy Roman Empire and two powerful states – Prussia and Austria – which had an interest in appealing to the national idea.

Napoleon's defeat was inflicted principally by the conservative regimes he had not conquered – Russia and Britain – rather than by national movements in areas he had. Even there, dynasties, state patriotism, hatred of the French, religious convictions, and opportunism better explain effective resistance. After 1815, there were attempts to restore privileges and old political arrangements. However, the map of Europe after 1815 was closer to that created by Napoleon than what had existed before. States were fewer and larger, more rationally and bureaucratically organized, with clearer boundaries. Governments could suppress national and liberal oppositions, but not the ideas that those movements embodied. Commercialization, even without industrialization, increased social and territorial mobility, which undermined attempts to restore privileges. All this pressured monarchies to shift toward constitutional forms of rule. New politicians emerged who appealed to the people or the nation (Baycroft and Hewitson, 2006; Colley, 1992; Dann and Dinwiddy, 1988; Greenfeld, 1992).

Nation-State Formation in Europe

Nation-state formation took place in three different ways: within preexisting territory (reform), by bringing together smaller states (unification), and by breaking away from a larger state (separation). These are artificial distinctions, but they draw attention to types of political movements and processes and provide a framework for analysis (Breuilly, 1993).

Reform

France and Britain had a national character by 1800, although rebellions in Ireland and the Vendée indicated that not all subjects agreed. Napoleon introduced legal, administrative, and other reforms, which over the nineteenth century helped overcome regional antagonisms, turning 'peasants' into Frenchmen. Vital was the development of mass education and politics. This took some time, marked by intense conflicts. Nevertheless, by 1900, although disagreements remained about the values to attach to the nation-state, all key political actors subscribed to the national idea and the priority of defending France against foreign threats.

In Britain, the 1707 union between England and Scotland, imperial growth, and the stress on Protestant resistance to Catholic threats shifted the national idea from an English to a British level. The Reform Act of 1832 doubled the electorate, established the House of Commons as the national center of power, and entrenched the two-party system. Following further franchise extensions, universal manhood suffrage was instituted in 1918, and universal adult suffrage in 1930. By 1870, elementary education was made compulsory and in the last decades of the nineteenth century there emerged a mass print media. Peasant and Catholic Ireland responded with separatist movements, but in the rest of the kingdom, the effect was to integrate politics and sentiments on national lines.

Similar processes can be observed in other 'state-nations' such as Spain, Belgium, the Netherlands (after the separation of the two territories in 1830), and the Scandinavian states. However, sometimes this was accompanied by regional resistance that took on a national form, e.g., Catalonia and the Basque regions of Spain (Hobsbawm, 1987; Pugh, 1994; Weber, 1979; Cabo and Molina, 2009).

Unification

German and Italian unification was marked by four features: a dynasty opposed to unification, a state promoting unification, a zone of small states, and neutrality or support from major powers. The growth of constitutional and popular politics meant that political movements increasingly appealed to the nation. Such movements were more important in Germany with suprastate institutions (Confederation of 1814; Customs Union of 1834) and more advanced economic development. Even here, national movements lacked mass support or access to state power.

The opposing dynasty was the Habsburg Empire. The revolutions of 1848 made that opposition very clear and revealed the weakness of popular nationalism. Elite nationalists turned to Prussia and Piedmont. The support of Louis Napoleon, British neutrality, and the weakening of Austrian and Russian capacities to resist change after the Crimean War all created the conditions for effective action against Austria. Cavour, Prime Minister of Piedmont, allied with France against Austria in 1859. The decrepit Kingdom of the Two Sicilies collapsed in the face of invasion by Garibaldi, extending unity to the south. The new state had little elite unity or popular support. As D'Azeglio put it: "We have made Italy, now we must make Italians."

Prussia became capable of acting against Austria after the 1859 war, Austrian crisis, and military modernization in Prussia. Yet Prussia as a conservative dynasty was reluctant to take up the national idea with its radical implications. However, Bismarck, Prime Minister of Prussia from 1862, was an unconventional conservative who believed that the national idea could serve the Hohenzollerns. In alliance with Austria he

exploited the mistakes of Danish nationalism to defeat Denmark in war in 1864 and bring Schleswig–Holstein under direct Austro-Prussian control. He maneuvered a war with Austria, helped by an alliance with Italy (engineered by Louis Napoleon), which was swiftly won. Prussian control was extended over northern and central Germany in alliance with liberal nationalists who helped to organize this political creation. French opposition to extension of control over South Germany was removed in the war against France of 1870–71. Italy exploited the wars of 1866 and 1870–71 to bring the Papal States and Rome into the nation-state.

The greater role of 'positive' factors of Prussian leadership and a national liberal movement compared to the 'negative' factors of state collapse and international support meant that regionalism was more quickly overcome compared to the Italian case. Nevertheless, Germany in 1871 was reluctant to embrace the national idea, as evidenced by the absence of a national anthem, the refusal to adopt the national colors of black–red–gold, and the rapid move into opposition of popular parties representing workers and Catholics. Both Germany and Italy required the same processes of industrial and urban growth, mass education, and politics, as noted for France and Britain, before a genuine nation-state could develop (Breuilly, 2011; Riall, 2009).

Separation

Military defeats weakened Habsburg's capacity to resist demands for internal change. In 1867, a new constitution gave autonomy to Hungary, converting the Magyars into a prop of the empire while depriving non-Magyars of support from Vienna. This intensified nationalist opposition, but Magyars maintained control, providing the outlet of individual assimilation into the dominant culture. In the western half of the empire, a Czech national movement had compelled the dynasty by the 1880s to make concessions at the expense of Germans. The Polish province of Galicia enjoyed much autonomy. Nationalist ambitions were checked by a combination of state power, reform, and the sense that full independence would create a small state at the mercy of powerful neighbors. Consequently, although national conflicts intensified in the Habsburg Empire, they did not directly threaten the empire before 1914.

By contrast, in the Ottoman Empire in Europe, national opposition was less the product of conflicts between ethnic/cultural groups and more the work of Christian elites seeking to replace waning Ottoman power. With assistance from European powers, motivated by self-interest and sentimental identification with Christian and national principles, this enabled the creation of separate states: Greece, Romania, Serbia, and Bulgaria. This stimulated a Turkish nationalist response that challenged the imperial Ottoman elite and in turn reinforced nationalist opposition, not only in Ottoman Europe but also among Arab subjects. Serbia supported national movements among 'its' national counterparts in the Habsburg Empire, which in turn stimulated Vienna to crush Serbia.

In Russia, there was an intensifying interaction between 'official' Russian nationalism and non-Russian movements. These remained weak, especially after the most significant, that of the Poles, was repressed in 1863. In Germany, there was Polish and Danish resistance to incorporation into a nationalizing state (Baycroft and Hewitson, 2006; Haddad and Ochsenwald, 1977; Okey, 2000).

Political Transformation

The trigger for transformation did not come from direct nationalist challenges to Habsburg and Romanov power, but from their responses to the new states in former Ottoman Europe. Austria sought to exploit the assassination of Archduke Ferdinand in June 1914 to bring Serbia to heel and Russia supported Serbia. Austria only acted as she did because of assurances of German support. Russia mobilized her alliance with France. Britain entered the war to prevent German domination in Europe. The success of nation building, especially in Britain, France, and Germany, meant that public opinion powerfully supported their nation-states.

Nationalist movements had little impact on the war. Rather, the defeat of Russia in 1917, and Germany, Austria, and Turkey in 1918, catapulted nationalism into prominence. The national idea was the legitimating principle of the Versailles peace settlement, as expressed in the 'Fourteen Point' program of the US President, Woodrow Wilson. Germany lost her Danish, Polish, and French acquisitions. The Ottoman and Habsburg empires were transformed into a series of nation-states in Europe and Allied mandates in the Middle East. Bolshevik Russia maintained control of non-Russian peoples, but incorporated the national principle into its ideology and institutions (Roshwald, 2001; Manela, 2007).

The new states were the product of great power diplomacy. They included national minorities. There were ethnic conflicts, even massacres. The result was a series of weak states that appealed to the core nationalism, persecuted national minorities, and whipped up discontent among their 'own' national minorities in other states.

These problems were compounded by global depression and the recovery of Germany and the USSR. The Allies could not guarantee the post-1918 order in East-Central Europe. Between 1936 and 1941, Germany and the USSR destroyed that order. With the German invasion of the USSR, the way was opened to the fantastic project of racial empire in Europe.

After Allied victory in 1945, the national principle was too entrenched to permit any alternative to the nation-state, although the principle was not applied to Germany, which was partitioned and occupied. However, states were grouped into supranational blocs under US and USSR leaderships. Many observers thought that the era of nationalism (especially when equated with fascism) and sovereign nation-states had ended in Europe, even if nation-state and national sentiment were firmly established (Brubaker, 1996; Dunn and Fraser, 1996; Payne, 1996).

Nation-State Formation beyond Europe

Nationalism and nation-state formation beyond Europe were responses to Europe. The earliest movements by settlers in the Americas utilized eighteenth-century appeals to political liberty and self-determination, but not the nationalist idea of cultural uniqueness. Americans did not yet see themselves as culturally

distinct from Europeans. The formation of distinctive national cultures was here, as in Europe, a nineteenth-century development associated with commercial, industrial, and urban growth. Similar patterns, although not accompanied by political revolt against the imperial state, mark other states dominated by large-scale white settlement. In Australia, New Zealand, and Canada, this led to the peaceful achievement of Dominion status within the British Empire, later membership of the British Commonwealth, and *de facto* independence, although disputes continue about remaining political ties, as evidenced by the 1999 referendum in Australia on the British monarch remaining head of state. In Canada and South Africa, the story was complicated by conflict between two different streams of European settlement – French and English, and English and Dutch, respectively. In Canada, this conflict remains politically important. In South Africa, the conflict became violent at the start of the twentieth century, but after the formation of an autonomous South African state in 1910 was increasingly replaced by conflict along race lines. This in turn ended with the end of apartheid and the achievement of black majority rule in 1994. In the Americas, Australia, and New Zealand, the precolonial populations were marginalized; in South Africa, this was not possible.

Neither was it possible where European domination was less through settlement than government and trade. Officials, missionaries, and merchants outnumbered white farmers, entrepreneurs, and workers. Colonial states were established in India and Africa. In large parts of Asia, notably China, power was indirectly exercised through client rulers.

There is a continuum rather than a sharp distinction between 'direct' and 'indirect' rule and 'formal' and 'informal' empire. Even an elaborate imperial bureaucracy as in India depended on informal agreements with indigenous elites. Areas of indirect rule were often marked by economic exploitation and cultural domination. Nevertheless, to understand the formation of nation-states, the distinction is important. Arbitrary boundaries imposed by Europe largely persist in the twenty-first century.

This suggests that the nation-state was the inheritor of the colonial state. Political movements formed within the colonial state, whether to oppose or collaborate. Such movements, using modern methods of political rallies, electoral contests, and print media, broke from precolonial patterns, appealing to the 'nation,' as subjects of the colonial state and as bearers of a distinct culture to set against European claims to civilizational and racial superiority.

Formal empire was largely constructed between 1858 (India) and 1900. Territory was transferred from the defeated to the victors of World War I. There were hardly any nationalist movements in these vast regions. Some opposition developed in the interwar period. Just as World War I created the basis for independence claims in Europe, so too did World War II beyond Europe. Japanese success in Southeast Asia and China abruptly destroyed myths of white superiority, although only to be replaced by a new and brutal imperial rule. Nationalist movements were divided as whether to ally with the old or the new imperial power.

World War II destroyed the empires of the defeated powers and fatally weakened those of the European victors. The United States and USSR denied that they were empires and promoted antiimperialist values. Imperial rule was restored by European countries, but was desperately weak. The United Kingdom had to quit India in 1947. Arab nationalism threatened British and French mandates in the Middle East. A uniquely complicating factor was the foundation of Israel in 1948. The crisis of 1956, when Israel, the United Kingdom, and France sought control of the Suez Canal, led to the withdrawal of US support for her Western allies and defeat for the United Kingdom and France.

From 1956, European withdrawal from Africa and the Middle East was just a matter of time. Nationalism became a politics of inheritance. Where political structures had promoted indigenous elites using modern political methods, decolonization was negotiated. Where this was blocked by white settlers or overdependence on direct economic exploitation, decolonization took place in chaos and violence, often with fateful consequences for the independent state. Decolonization is not the same as removal of cultural or economic power. Indeed, some regard decolonization as an imperialist trick. New forms of nationalism developed, stressing economic independence and cultural authenticity rather than 'mere' political self-determination.

In the Middle East, Southeast Asia, and elsewhere, the story is complicated by the emergence of the United States as an imperial power, even if indirectly exercising power. This was partly due to fear of communist expansion, partly to support for client states (e.g., Israel), and partly to protect economic interests. Whatever the reasons, it stimulated anti-American nationalism. This remained tied to existing state boundaries. Nationalists in Tunisia, Libya, Algeria, Egypt, Syria, and Iraq espoused Arab nationalism, but jealously maintained state independence. Vietnamese antiimperialists turned to communism, but never ceased to distrust China. This is not to argue that ancient national rivalries predate and trump other sentiments, but rather that the colonial state and its successor provided the framework around which nations formed.

Important regions not subject to formal empire were Japan and China. In Japan, a unique transition took place from feudal/decentralized to imperial/centralized state, similar to the European pattern and partly in reaction to Western threats. The assertion of autonomy was couched in national terms. Japanese modernization was sufficiently advanced to lead to successful war against Russia in 1904. This is perhaps a unique case of modern nation-state formation without European involvement, although Japan's post-1945 history has been shaped by defeat and American occupation.

The subjugation of China to indirect Western rule produced nationalist rejection of the corrupt empire and alien influences, leading to the formation of a republic in 1911. However, nationalists had little control over much of China, which was run by local warlords, and this inhibited appeals to the 'people.' This appeal came from communists, although the 'people' were constructed in class, not in national, terms. The Japanese invasion of China tilted the balance of power from nationalists to communists, enabling the communists to appeal to anti-Japanese sentiment as well as class interest. Thus, Chinese communism had a nationalist element, which in turn shaped the state it established (Anderson, 1998; Breuilly, 2013; Brown, 1985; Darwin, 1988; Antlov and Tonnesson, 1996).

Nations in a World of Nation-States

After 1945, the nation-state appeared both less and more important than previously: more important as the accepted political unit and because forced population transfers, mass murder, and boundary changes since 1918 had created more ethnically homogenous populations and less important because of the discrediting of nationalism and the emergence of supranational blocs.

The result was 'banal nationalism.' National identity was presented as something 'natural,' separate from 'politics.' National rivalry was displaced from politics into cultural contests. How far such sentiments can be politically mobilized is questionable; after a few years of casualties in Vietnam, it was difficult to sustain popular support for the US war effort. Nevertheless, sentiments of national identity are transmitted everyday through mass media. The banality of the idea means that no political actors can disavow national values, but equally they have little specific political content (Billig, 1995).

There are two major exceptions to this. First is the emergence of regional national movements in Europe and Canada. Some have gained regional autonomy, often the goal rather than the dangers of independence, and something central governments felt able to concede, often as part of a more general decentralizing political process. It is difficult to generalize about these movements that do not appear as part of a general trend, but represent specific problems in individual nation-states.

Second is the collapse of the Soviet Union. The Warsaw Pact states gained real independence, while also abandoning communism, if not authoritarian rule. Non-Russian republics in the USSR declared independence. Regions within Russia asserted claims against Moscow. Russian nationalists resented the loss of imperial power and sought to retain and regain territory and offered help to 'Russians abroad.' Has the collapse of the USSR unleashed a new wave of nationalism?

Nationalism arguably contributed little to the collapse of the USSR, which was principally due to economic crisis and destabilizing political reforms. National movements were a response to that instability. The issue was less about national independence than the form of the post-Soviet state. Answers varied along a continuum from old-style communism through reform communism, takeover by popular leaders, dissenting intelligentsia or nationalists, to disappearance (East Germany). Each can change, e.g., as electorates shift between market-oriented liberal reformers and protectionist, socialist restorers. The nation-state is the political unit within which these politics are practiced, including seeking closer association with Western Europe, especially through entry into the European Union. The great exception was the violence that accompanied the collapse of Yugoslavia. Does this show that nationalism was stronger in Yugoslavia than in the USSR? Arguably, the crucial difference was that Russia led by Yeltsin did not resist, but indeed led the dissolution of the USSR, whereas Serbia, led by Milošević, resisted the breakup and, along with Croatia, sought to enforce territorial claims on other former Yugoslav republics.

In non-Russian republics, the first nationalist outbursts leading to independence subsequently subsided. In Ukraine and Moldova, ethnic nationalism gave way to a stress on the national character of the territory and all its inhabitants. Russian minority problems in states like Estonia became matters of negotiation in ways pessimists had not thought possible. In Russia, major conflicts revolve around economic interests and democratization, rather than nationalist issues.

That does not mean nationalism is unimportant. There are non-Russian areas where military-based movements claim autonomy by violent means, notably Chechnya. Russian nationalism has been inflamed by Western intervention. Festering disputes remain between Russia and former republics. Muslim sentiments can fuel separatist movements, especially in mountainous and inaccessible areas. Nevertheless, in much of the region, political geography seems fairly settled.

Just as one can exaggerate nationalist conflict in Eastern Europe, so can one underestimate it in Western Europe. Many features of the 'classic' nation-state are being superseded. European Union nationals are semicitizens in other EU states. Settled immigrant workers possess legal and social rights. National governments shift from policies of cultural assimilation or exclusion to those of multiculturalism. Governments cede powers to EU institutions. Nevertheless, the most important EU institution is the Council of Ministers, that is, delegates of national governments. While most people remain largely confined to their national language and territory, they will regard themselves 'naturally' as national, something routinely reinforced through mass media. Nationalism as the basis of the organized pursuit and use of state power may have passed its peak. Nations as communities and nation-states as their protectors are still regarded as natural and remain of central importance. The current Eurozone crisis inflames nationalist sentiments and this seems likely to grow in importance (King, 2010; Kupchan, 1995; Smith, 2005).

Nation-State and War

Abstract

Conscription transformed how wars are fought, making possible far larger armies and bloodier conflicts. Conscription also changed the relationship of citizens to their nation, allowing soldiers and their families to claim civil rights and social benefits and to demand that their sacrifices be recognized and honored, transforming how war dead are memorialized. The history of conscription, which began with the American and French Revolutions, is now ending in the West, with consequences for how wars currently are fought.

War before Nation-States

Wars, for most of human history, were not fought by nation-states. Men (and it almost always has been men who have fought) identified with and went to war for their kin group, tribe, religion, or ethnic group. Such committed fighters were not military professionals; they were farmers or townspeople, and therefore were available to fight only for short periods of time and near their homes.

The limits of wars fought by part-timers can be illustrated by the ancient Greeks, who left better records than most. Their wars have been analyzed in most detail by Victor Hanson (1989). He finds that while the Greeks tried to kill as many of the enemy (soldiers and civilians) as they could, they also wore heavy armor to protect themselves, which exhausted their wearers in a few hours, and the citizen-soldiers returned to their farms or cities, or to the ships that had transported them to another Greek island, literally, at the end of the day. Greek and other premodern soldiers generally fought only when they were not needed on their farms.

If rulers wanted to fight sustained wars over long distances they needed to recruit aristocrats and their retainers or hire mercenaries. Both those avenues for building armies were problematic. Premodern polities were not unified. Rulers for the most part could not command aristocrats within their 'kingdoms' to fight in wars when and where the king commanded. Instead, rulers had to entice aristocrats to join them in battle. Aristocrats, in turn, had to entice lesser aristocrats to bring their armed men to war. In battle, aristocrats kept command of their own armed men. As a result, 'armies' were not cohesive fighting forces and often fought at cross-purposes with disastrous results. If an aristocrat decided he no longer agreed with the goals or strategy of the war, he could take his men and go home.

Aristocrats' low commitment and generally poor fighting ability led rulers to hire mercenaries as a substitute or supplement for the retainers nobles brought to battles. However, mercenaries' willingness to fight depended entirely on a king's ability to pay them. Mercenaries were fungible: they varied little in their level of skill, and with rare exceptions their commanders lacked the strategic brilliance that would allow them to achieve a decisive victory with a smaller army than their opponents. Technological innovations were quickly copied. Thus, money ultimately was the key to victory.

Rulers, before the era of nation-states, had no reliable method for procuring revenues. Aristocrats and clerics were as reluctant to share their incomes with kings as they were to commit their armed retainers to a monarch's war. Rulers lacked bureaucracies that could collect taxes from their nominal subjects. The best way to extract revenues was by using armed men, who could be used to threaten towns and villages with destruction and death unless they met the king's demands for taxes, or who could be sent into battle to conquer new territories that could be looted or incorporated into the rulers' kingdom and then forced to pay regular tribute.

The conundrum was that rulers needed money to hire the mercenaries that were required to collect money. The process of building armed forces and then bureaucracies to collect revenues was slow and uneven. Charles Tilly (1990), whose 'fiscal-military model' best identifies the patterns in this centuries-long process, notes that cohesive polities formed first in areas with commercial activity that could most easily be identified and taxed, and later spread to areas with aristocracies that could be enlisted to tax settled peasant communities. The rulers with the most success at appropriating revenues created armies that were larger than those of neighboring rulers whom they then could defeat and absorb their territories. In this way, Europe was transformed from a continent with over 500 political units in 1500 to one with fewer than 30 in 1990.

The armies premodern rulers cobbled together with nobles and their armed retainers and the mercenaries they could afford to hire were small; the largest had tens not hundred of thousands of troops. Although, at least in Europe, the trend was toward territorial consolidation, most battles and wars did not reach conclusive ends that permanently altered the borders of the combatant polities. Instead, wars often petered out after years or decades, ending in an agreement to return to previous borders, a repatriation of prisoners, or payment of ransom for a captured king or great noble. The famous conquerors of the ancient world, such as Alexander, Genghis Khan, or Tamerlane, in fact did more looting than conquering. Their empires came apart after their deaths, as heirs and generals grabbed portions of the conquered lands for themselves. The Roman and Chinese empires were exceptional in world history for their size and durability. Those two empires achieved success by creating a unified Roman army and Chinese bureaucracy; however, both those institutions were sustained by granting local garrisons and officials a high level of autonomy in return for not

 http://dx.doi.org/10.1016/B978-0-08-097086-8.96041-0

challenging central authority and sending a fraction of their revenues to the imperial capital. Neither empire was a cohesive polity in the way that modern nation-states are.

War throughout most of human history was not an activity in which most men participated, and when they did it was a part-time task. Nobles, who made up 1–2% of the population, and mercenaries were the only professional soldiers. This pattern was to change with the advent of nationalism and nation-states.

Creating National Armies

Conscription was invented out of desperation. The revolutionary American and French governments, both about to be crushed by the overwhelming financial and military power of Great Britain (alone in the former case, and in alliance with all the other major European powers in the latter) issued calls to ordinary citizens requiring them take up arms to defend their new republics. Conscription created nationalism as much as it drew legitimacy from citizens' already existing feelings of national identity.

Service in a national army brought soldiers together with men from elsewhere in the polity, creating intense feelings of membership in a collectivity, the "sense of a deep, horizontal comradeship" (Benedict Anderson [1983]1991, p. 7) sees as the essence of nationalism, and that extended far beyond the lineages, occupational groups, religious communities, and localities that were the limits of almost all humans' feelings of solidarity until the American and French Revolutions. As Meyer Kestnbaum, the sociologist who has studied the origins of conscription, writes, "Citizen conscription … help[ed] consolidate a politically mass-mobilizing regime … by rendering all citizens formally equal … by integrating them and their state into a single polity … by politicizing them, their relations to one another, and to the state" (2002, p. 131). In essence, conscription was a deal between a regime and its subjects. In return for serving in the military, and risking their lives, subjects became citizens, with rights that residents of a polity who were not members of privileged groups had never before received. The process of gaining those rights was contested and uneven, as we will see in the next section.

The commanders of armed forces realized that, in addition to offering citizen rights and benefits (salary, medical care, pensions, education), they needed to instill nationalist sentiment and understanding in recruits if they wanted them to fight with fervor. For most Europeans of the nineteenth century, their first significant interaction with government officials from beyond their localities came when they were drafted into the military. In addition to training for war, recruits and draftees were taught the national language, which became the working language of the armed forces, and often were given lessons in the civics and history of the state they served. Governments in Asia, Africa, and Latin America have undertaken similar efforts to teach and foster nationalism in their soldiers.

Militaries that were able to draw on nationalism to conscript soldiers, and then succeeded in deepening the nationalist sentiments and fighting fervor of their troops, enjoyed a decisive advantage over armies that still relied on aristocrats and mercenaries. First, conscription severed the link between tax revenues and army size. The French revolutionary army was larger than those of all its antagonists combined in the 1790s, and most importantly, even after massive casualties, it could be replenished with new rounds of draftees. Second, draftees were much less likely to desert than mercenaries and aristocrats, who fought only as long as they were paid or while their patron or noble faction remained in alliance with the king. In contrast, conscripts were pulled into the army by legal obligation to serve (which was not the case for either mercenaries or aristocrats and their retainers). While the nationalist fervor that often attracted soldiers into service generally faded under the grind and horror of battle, it was replaced by a desire for vengeance against the enemy who was killing their fellow citizen-soldiers. Above all, once militaries were able to draft soldiers and keep them in the field for months or years, they were then able to move conscript armies far from home. In essence, conscripts were marooned on the battlefield, unable to return home until their army had won or lost the war. As conscripts spent long periods together, they developed loyalties to the fellow soldiers in their company or platoon, and then fought to help each other survive and to avenge the deaths of individual soldiers with whom they lived and fought. Armies came to realize that soldiers fought better if their commanders fostered solidarity at the platoon level.

Conscript armies revolutionized military strategies. Eighteenth century commanders had developed fighting techniques that relied on soldiers who were well trained, frequently drilled, and willing to obey their officers' orders. However, until the advent of conscription those techniques could not really be implemented. Mercenaries and aristocrats generally did not serve long enough, and almost never showed up long enough before battle, to be trained and drilled in the new battle tactics. Nor were mercenaries and especially aristocrats willing to follow orders.

Despite all the advantages of conscript armies, most European countries refused to institute the draft. Aristocrats often had enough political power to prevent reforms that would undermine their control over armies. Kings and aristocrats also feared that subjects who were armed and trained to fight could turn on their rulers. Yet, repeated victories by conscripts over aristocratic armies eventually led governments to adopt the draft. The US Civil War was the first war in human history in which both armies were manned by conscripts. By the time of World War I all European armies relied on conscripts, except for Britain, but even Britain had to institute the draft after its volunteer armies were destroyed in the first years of trench warfare.

Conscripts were willing, or could be compelled, to train, drill, and fight in ways that exposed them to much higher risk of death than aristocrats or mercenaries had been willing to tolerate. This led to a further military revolution, as commanders gave priority to killing the vastly larger enemy armies they now faced. Once an enemy had access to almost limitless numbers of fresh troops, it became essential to kill as many of the enemy as possible. Armies sought to develop weapons able to do that. Militaries invested resources in creating more powerful weapons. The machine gun, for example, as John Ellis (1975) has shown, was first developed to allow a few Europeans to kill and intimidate large numbers of natives in Asian and African colonies. However, the few

available machine guns at the start of World War I proved most effective at killing large numbers of enemy troops and both sides then purchased huge numbers of the guns, which along with poison gas and shells, turned World War I from a war to capture territory into a war to annihilate the enemy's entire armed forces. This logic was carried to its ultimate conclusion in World War II, as the Allies and Axis both targeted civilians. After all, civilian men could be called up in future rounds of the draft, and civilian women could produce babies who could become soldiers in later years. This culminated in the annihilation of entire cities, and remains the logic behind countries' manufacture of and planning to use nuclear weapons.

Citizen Armies and Soldiers' Rights

During and after wars, soldiers and their families made demands on the governments that forced them to fight and that exposed so many of them to injury and death. Benefits such as old age and disability pensions, health care, and other forms of social insurance, which were generally offered first to government employees, were then extended during and after wars to conscripts and veterans. Often the rest of the population had to wait decades to obtain, or still have not received, the benefits given to soldiers.

The US created a system of pensions for veterans and their widows after the Civil War that preceded the universal social security system by seven decades. Theda Skocpol (1992) shows that Civil War pensions became the largest item in the federal budget by the end of the nineteenth century. At the end of World War II, US veterans received subsidized home mortgages, unemployment benefits, and free university educations through the Servicemen's Readjustment Act of 1944 or G.I. Bill. These benefits, which later were offered in modified form to the entire population, made the US the world's leader in home ownership and, until the twenty-first century, in the fraction of young people with university educations. In other domains, benefits offered to veterans have not been extended to others: in the early twenty-first century, soldiers remain the only Americans who have access to guaranteed day care for their children.

Many European, Latin American, and Asian countries also modeled their social programs on benefits first given to soldiers and veterans, although in most of those countries benefits were extended much more quickly to the rest of the population than they were in the US. Often the rest of the population laid claim to social benefits by arguing that they shared in soldiers' sacrifices. Mothers who gave birth to and raised sons had the most compelling claims to civilian benefits.

Soldiers and their families also demanded voting rights. John Markoff (1996) finds that worldwide waves of democratization occurred at the end of both World Wars. This encompassed the extension of civil liberties and voting rights to excluded classes and ethnic and racial groups, women and youth, and expanded rights to those who already were full-fledged citizens. Markoff argues, correctly, that the World Wars empowered women's and labor movements, which won voting rights and other concessions in return for their commitment to munitions factory work and willingness to forgo strikes to ensure the delivery of critical supplies of weapons during the wars. Those practical deals were fortified as well by the moral claims women made to citizenship as the mothers and wives of soldiers.

Conscription, and the extension of social benefits and voting rights changed the meaning of national identity. Conscription turned subjects into citizens. Citizens were obligated to protect the nation of which they were a part, an obligation expressed primarily by years of service in the military and the risk of injury and death in that service. However, in return soldiers and their families were part of the nation and received the benefits of citizenship. Their basic needs – a minimum income when they were unable to work due to age, disability, or unemployment, access to health care, education, housing, child care – were part of a growing list of needs which their nation's government became obligated to provide. As citizens, soldiers, and their families demanded a role, through the right to vote, in determining when and where their nation fought wars, and in all the other decisions, including the provision of social benefits, once made by rulers or narrow elites.

Obviously, conscription was not the only spur to voting rights and social benefits. The US stands as an example of how benefits granted to soldiers are not necessarily quickly or ever granted to the rest of the nation. Voting rights and social benefits also were the product of struggles led by working classes, minorities, women and other popular forces, and organizations. However, the vast reach of social programs and the universal franchise in many countries would not have been possible without the claims made by soldiers and their families and the openings that wartime mobilization created to press those claims against governments that were fighting for their survival and therefore were desperate to secure the consent and willingness to sacrifice of their citizens.

Conscripts and their families also made another sort of claim upon their governments: for recognition of their sacrifices. Before the era of conscription, governments made no efforts to memorialize dead soldiers. Memorials were meant for commanders. Triumphal arches were built for generals; victory parades honored the generals not the soldiers. Nor did governments even attempt to count the number of their soldiers who were killed or injured or to inform families of the fates of their loved ones. When soldiers failed to return from war, their families often did not know if they had died or just had decided to settle elsewhere.

The US Civil War, the first war fought between two conscript armies, began a fundamental transformation in memorializing war dead. For the first time a government assumed the obligation of identifying all the war dead, recovering their bodies, and informing families of those deaths. The dead were then buried in national cemeteries without distinction as to military rank, religion, or ethnicity (although until the middle of the twentieth century African-Americans were buried in separate sections of most US military cemeteries). Britain, France, and Germany continued to separate soldiers by rank in their military cemeteries until the end of World War I. The magnitude of death in that war, as for Americans in the Civil War, led soldiers' families to demand, and governments to recognize, the equality of their sacrifices, treating all dead citizen-soldiers equally.

These American innovations were copied by other nations that conscripted soldiers. The Arc de Triomphe traces the evolution of war commemoration. It was originally designed, following the model of imperial Roman triumphal arches, to mark Napoleon's victory at Austerlitz in 1806, and only generals' names were carved on it. After World War I it became the site for the Tomb of the Unknown Soldier, which in France and in all other countries with such tombs, symbolizes the nation's commitment to honor every one of its war dead.

The commitment to honor all the war dead became an effort to actually find and identify each soldier's body. If soldiers were to be buried, their bodies had to be recovered from the field of battle. The US and other countries have taken increasingly elaborate measures to ensure that all bodies were accounted for. After the difficulty of identifying bodies left on battlefields in the Civil War, the US and other countries made use of 'dog tags' in World War I, giving each soldier a metal disk with their name and other identifying information to be worn at all times so that their bodies could be identified. More recently, DNA testing has allowed even the tiniest body fragments to be identified, and governments have undertaken the task of finding and testing such fragments to determine the identities and place of death of formerly unknown bodies and to link them with soldiers classified as 'missing in action.' The often extreme and expensive efforts to recover bodies and body fragments (the US still is attempting to do so in Vietnam, four decades after the end of the war) are an indication of how seriously soldiers' families take this obligation and how strongly they hold governments to it. Similarly, soldiers are expected to try to recover the bodies of their dead comrades from the field of battle, even at the risk of their own lives. This imperative, which became central to concepts of military honor in countries as they adopted conscription, is yet another way of indicating the fraternity and equality of citizen-soldiers.

The Demise of Conscription

The two-century history of conscription is coming to an end, at least in the West. States' capacities to convince or compel its citizens to risk their lives, or even to give a few years of service, for their country have declined dramatically in Europe and the United States since World War II, and might decline in much of the rest of the world in coming years as well.

Commitment to military service has fallen at the most basic level: countries first moved in recent decades to reduce the length of military service and offer more exemptions to students and conscientious objectors, and then abolished the draft entirely. The status of conscientious objectors has changed most dramatically in Europe: from World War I, when, as Nicoletta Gullace (2002) documents, British men who did not serve were publicly humiliated by women who pinned white feathers on them, fired by employers, and stripped by Parliament of the right to vote at war's end, to the late twentieth century, when beginning in the 1970s the Universal Declaration of Human Rights was reinterpreted to encompass conscientious objection and Amnesty International adopted jailed conscientious objectors as prisoners of conscience.

The draft was abolished entirely in Britain in 1960, Australia and New Zealand in 1972, the US in 1973, Belgium in 1994, France and the Netherlands in 1996, and in much of the rest of Western Europe and most of the former Soviet bloc in the first decades of the twenty-first century. Russia is in the process of abolishing its draft. While Israel still has universal service (and is the only country in the world ever to draft women), a growing percentage of young people are being allowed to leave military service after a few months rather than fulfilling their full legal obligation.

The European and American abolition of the draft is a rejection both of the sense that young men should be obligated to devote time to national service and also of the belief that nations face threats that deserve to be countered at the cost of their citizens' lives. The most common explanation for this rapid and a dramatic change comes from Hanson (2010, p. 242): "Western medical science not only ensures longer life, but, through the use of sophisticated pharmaceutics and artificial body parts, also promises an enjoyable longer life. Those advances will make it ever harder to ask a small minority of our citizens to lose their lives to ensure longer and better ones for the rest of us. Most twenty-first century Westerns do not see death on their streets. They do not butcher the animals they eat. And they do not lose a large minority of their children to disease and hunger before the age of twelve." Leon De Winter (2007) argues: "Today's parents often have no more than two children, some may have only one son. His life is so precious that it has come to seem unbearable for him to be killed in battle." If this theory is correct, we can expect to see an end to conscription, and greater resistance by citizens to allow themselves or even volunteers to fight and die in wars, in countries such as China and Iran which are experiencing rapidly falling birthrates.

Parents' and all citizens' aversion to death is magnified by the increasing attention governments, the media, and citizens pay to the individual soldiers who die in war. The increasingly personalized and elaborate memorialization of the dead, which we examined in the previous section, serves to magnify each death for the public at large and makes it more difficult for voters to agree or governments to demand that citizens submit themselves to conscription and risk their lives in war.

The Future of War

The end of conscription is drastically transforming states' capacities and strategies for fighting wars. Without conscription, states are forced to rely on volunteers. As the supply of soldiers shrinks, strategies that depend on tolerating massive casualties to gain territory or on long wars of attrition are no longer possible. As a result, Western nations practice what Martin Shaw (2005) has labeled "risk-transfer war" in which the cardinal rule is to minimize one's own casualties even if that increases civilian casualties in the foreign lands where Western nations fight.

States have developed technologies and strategies to minimize their own soldiers' casualties. Drones and other remote-controlled smart weapons are the most prominent technological fixes. However, despite the claims of governments that drone attacks are carefully planned to hit only military targets and that civilians are rarely or never hit, in fact

the main purpose of such weapons is to protect soldiers from one's own country, not civilians in the territories under attack.

High-tech weapons are useful only for certain sorts of attacks: ones that target a relatively small number of enemy fighters. They are not effective for controlling territory or subduing large populations. In any case, such weapons are effective only if the attacking force has access to intelligence on the ground, and that requires having live soldiers or spies in place who are then vulnerable to attack. When drones hit civilians they inevitably anger the local population, undermining efforts to win locals' 'hearts and minds.' Thus, risk-transfer strategies make it more difficult if not impossible to win wars that require winning the loyalty or at least acquiescence of the local population.

Armed forces dedicated to minimizing their own casualties become vulnerable to and distracted by insurgent strategies. Soldiers are captured or taken prisoner in almost all wars. In the long era before nationalism, governments only made efforts to ransom kings or high nobles, and cared not at all if common soldiers were imprisoned or even enslaved by their enemy captors. With the advent of conscript armies of national citizens, the recover and decent treatment of prisoners of war became an obligation that governments took seriously. When governments slacked in their efforts to recover prisoners, captured soldiers' families agitated for their release. This gives insurgent forces a powerful source of leverage. When they capture enemy soldiers they can hold them for substantial ransoms. The current Israeli practice of trading 1000 Palestinians, whom the Israeli government considers terrorists, for a single kidnapped or captured Israeli soldier, a practice supported by large majorities of the Israeli population, is emblematic of how efforts at casualty minimization affect governments' military strategies. If troops need to be positioned to ensure they are not captured, battlefield tactics are severely limited, just as medieval armies that gave top priority to protecting their king or noble commander were hampered in war. And of course thousand to one trades counteract an army's goal of neutralizing as many enemy fighters as possible.

Casualty minimization already forces governments to restrict their foreign policy goals to ones that can be accomplished with high-tech weapons, and inevitably will continue to do so in the absence of a return to conscription. The US and European nations' decision not to intervene to stop the Rwandan genocide was an accurate reflection by those governments of their publics' unwillingness to tolerate casualties to save civilians in a distant nation. Similarly, the decision to intervene in Bosnia with high-altitude bombing that sacrificed local civilians for the safety of NATO pilots reflects the same calculus.

Nationalism, thus, elevates the value of one's own citizens at the same time as it devalues the lives of foreigners. In the World Wars, this was expressed in support for massive attacks on civilian populations in enemy countries. Today, it is expressed in extreme solicitousness for the soldiers of one's own nation and an almost absolute unwillingness to sacrifice even a single life of one's countryman to save large numbers of civilians abroad.

If the present emphasis on protecting the lives of one's own soldiers above all other considerations continues governments will fight fewer wars. Militaries will exist mainly as deterrents against improbable attacks upon the nation's home territories and as symbolic representations of the nation. That does not mean wars will end. Nonstate actors, and states where nationalism is weak or where it is not expressed in concern for the lives of each soldier as an individual, will continue to be able to fight wars. Governments concerned with casualty minimization are likely then to intensify their efforts in 'homeland security,' in an effort to keep the violence of nonstate actors at bay. Israel offers a model of this approach. Its security wall and related measures are a highly successful (at least until now) strategy to protect Israelis, in settlements in the occupied territories as well as in Israel proper, from attack. Combined with the threat and use of massive retaliation against its enemies, Israel has managed to deter and deflect attacks despite continuing to hold and build settlements in the West Bank. This is the future of warfare in modern nation-states.

Nationalism, which in the nineteenth and twentieth centuries, made possible warfare and casualties on a scale never seen in human history, today is undermining states' capacities to enlist soldiers and place them at risk of death. The geopolitics made possible by mass armies of draftees is being transformed as conscription and tolerance for casualties disappears from more and more countries.

Nation-State as Symbolic Construct

Abstract

Research on nationalism has been especially preoccupied with those aspects of the phenomenon that are most destabilizing for existing institutions, thereby assuming that in the absence of violent upheavals, nationalism in established democracies is simply a *fait accompli* rather than a source of continued social and political change. In contrast, more recent studies have turned their attention to everyday forms of nationalism, arguing that the primacy of the nation-state as a unit of political governance and collective identification is continually reinforced – and sometimes subtly altered – through routine cognitive and affective orientations that are themselves products of institutional and ritual practices. This article provides an analytical overview of this literature, identifying its contributions, limitations, and potential for achieving a more complete understanding of nationalism in contemporary societies.

Introduction

Nationalism is one of the central ideologies of the modern era. Not surprisingly, its hegemonic rise over the past 200 years has attracted considerable attention from historians, sociologists, and political scientists. Researchers have been especially preoccupied with those aspects of nationalism that have been most disruptive for existing social and political institutions, from the emergence of collective identification in newly forming nation-states and the struggle for statehood by minority groups to the sudden eruptions of nativism and xenophobia in otherwise stable societies. Much of this literature has been based on the implicit assumption that in the absence of violent upheavals, nationalism in established democracies is simply a *fait accompli* rather than a source of continued social and political change.

In contrast, more recent studies have turned their attention to everyday forms of nationalism, arguing that the primacy of the nation-state as a unit of political governance and collective identification is continually reinforced – and sometimes subtly altered – through routine cognitive and affective orientations that are themselves products of institutional and ritual practices. Such work has shown that meanings attached to the nation are not uniform within a given national community, but systematically vary across individuals and social groups and are associated with other socially and politically relevant attitudes and behaviors. This article provides an analytical overview of this burgeoning literature, identifying its contributions, limitations, and potential for achieving a more nuanced understanding of nationalism in contemporary societies.

Traditional Nationalism Scholarship

The majority of research on nationalism falls within three broad traditions that investigate the origins of the nation-state as an institutionalized political form, the rise of new independent nation-states in the post-War period; and radical nationalist ideologies in contemporary societies.

Focusing on the historical emergence of the nation-state, the first approach is grounded in the observation that prior to the eighteenth century, the political authority vested in statelike institutions was rarely absolute or uncontested. Most states ruled over diverse populations sharply divided along lines of ethnicity, cultural tradition, religion, and language. It is only with the rise of the modern nation-state and its constitutive ideology of nationalism that state sovereignty became codified in both a territorial and cultural sense, with state subjects increasingly viewing themselves as members of a community with shared descent, customs, and collective fate (Gellner, 1983; Anderson, 1983). In the process, the nation became the source of the state's legitimacy and the congruence of the state's political and the nation's cultural boundaries became a taken-for-granted reality. Of course, this process was far from teleological; the rise of the nation-state came in fits and starts and was accompanied by protracted conflicts and institutionalized forms of intergroup domination.

The second tradition documents the rise of independent nation-states in the post-War period, most recently during the postcommunist transition in Eastern Europe. This literature is rich in case studies, but has been less effective at formulating general conclusions about nation-state formation and diffusion. Among the exceptions is Hechter's (2000) *Containing Nationalism*, which argues that nationalist movements are mobilized by centralized states' direct rule over culturally heterogeneous but territorially bounded populations. Viewing this as a problem for state stability, Hechter advocates policies that grant autonomy to minority populations. Another important theoretical contribution is Brubaker's (1996) study of ethnic relations in former Soviet republics and satellite states, which he sees as characterized by three distinct types of nationalism: 'nationalizing nationalism' of the newly sovereign states, 'minority nationalism' of domestic minority groups, and 'homeland nationalism' of coethnics in bordering countries. The interaction between these three political forces gives rise to state-driven social exclusion, oppositional struggles for minority rights, and occasional eruptions of violence directed against states and their majority populations.

Finally, the third body of literature focuses on radical nationalist movements. Rather than aiming to reconfigure the political boundaries of existing nation-states, these movements attempt to mobilize members of dominant groups to resist changes to the nation's symbolic boundaries brought on by

immigration or the extension of rights to oppressed native-born populations. These mobilization efforts are typically motivated by racially, ethnically, or religiously essentialist conceptions of the nation that explicitly exclude entire categories of people based on ascribed characteristics. Much contemporary research in this tradition focuses on Europe, which has experienced a resurgence of radical right-wing politics with strong ethnic nationalist tendencies (Taggart, 2000; Mudde, 2007; Bale, 2013). A distinct but substantively related line of research on the United States has focused on the country's long history of exclusionary politics based on nativist, racist, and fundamentalist ideologies (Higham, [1955]2002; Burris et al., 2000; Blee, 2002).

The above three approaches have generated many rich insights about the origins and continued importance of nationalist ideology in modern society. Yet, this classic work has largely ignored the more mundane – but no less important – aspects of everyday nationalism in stable democratic countries.

Nationalism in Settled Times

As a growing number of studies have demonstrated, the political significance of nationalism is not limited to periods of major political transformation or national crisis; nationalism exerts distinct effects on political change in settled times, although its impact is likely to be more subtle (Swidler, 1986). To understand this process, the analytical lens must shift from explicit political ideologies to tacit understandings of the nation's symbolic significance within a given polity. While most citizens of contemporary societies take for granted the legitimacy of the nation-state form, they often disagree in important ways about what their nation-state means to them. This variation – both within and across populations and over time – is an important feature of political culture that influences political behavior and drives policy change. Scholars have explored this dimension of nationalism from two vantage points: first, historical, ethnographic, and interpretive studies have explored the meaning-making processes that produce and maintain national identification; second, survey-based research has sought to map the variation in nationalist attitudes within and across populations and to demonstrate the impact of these attitudes on other political beliefs. Together, these approaches have laid the groundwork for a more complete understanding of nationalism in politically settled times.

Interpretive Studies of Everyday Nationalism

A long line of work in political sociology and political science has focused on how meanings attributed to the nation affect people's self-understanding and how such conceptions relate to a given country's overarching political culture. Classic studies in this tradition were based on a functionalist understanding of culture as a coherent system of agreed-upon values that facilitates social cohesion; this logically implied that the task for nationalism scholars was to uncover each nation's essential and stable cultural characteristics. For instance, in *Continental Divide*, Lipset (1990) argues that the national identity of the United States consists of the central tenets of the American Creed: antistatism, individualism, populism, and egalitarianism. In contrast, Canada – Lipset's comparison case – prioritizes a distinct set of principles, including deference to authority, collectivism, elitism, and group-based particularism. Such large-scale cultural generalizations were typical of post-War scholarship, as exemplified by the work of Myrdal (1944), Hartz (1964), and the broader enterprise of consensus history.

An influential legacy of the functionalist approach has been the distinction between ethnic and civic nationalism, initially made by Friedrich Meinecke ([1907]1970) and subsequently elaborated by Hans Kohn (1944). This binary opposition assumes a stable character to national identity, but differentiates between two alternatives: the first based on ascriptive criteria such as race, ethnicity, ancestry, religion, or language and the second on elective criteria, such as commitment to the country's core ideology, subjective identification with a national community, and respect for the nation's laws and traditions. This dichotomy has been used to classify the central ideologies of specific nations – with Germany as the prototype of ethnic nationalism and France of civic nationalism – and occasionally entire world regions.

The view of national culture as stable and homogenous has been challenged by more recent research. Rogers Smith's (1997) work on citizenship law in the United States, for instance, reveals a layered and often contradictory patchwork of legislation and court decisions informed by three distinct ideological perspectives (i.e., liberalism, republicanism, and 'ascriptive Americanism'), which have competed for dominance over the course of American history. Others have critiqued the ethnic–civic distinction on theoretical and empirical grounds for attributing essential properties to entire countries and regions and glossing over considerable within-country heterogeneity (Kaufmann, 2000; Shulman, 2002; Brubaker, 2004; Ceobanu and Escandell, 2008).

Despite its limitations, functionalist research on national identity has generated a number of valuable insights. Perhaps most importantly, it has helped scholars recognize that even though nationalism has become a hegemonic ideology in modern society, the content of nationalist beliefs can be highly variable. This work has also highlighted the inherent tendency of nationalism toward social exclusion: given that nationalism is predicated on a fundamental belief in the unique characteristics of each nation, it inevitably draws sharp symbolic and social boundaries around national communities based on a range of arbitrary criteria. Of course, the need for distinguishing between members and nonmembers is necessary for every state's ability to fulfill its core functions, such as generating tax revenue, managing economic development, providing social programs, and ensuring national security, but how such distinctions are made and maintained is an important object of study.

While the functionalist approach attempted to identify the shared attributes of a given political culture, more recent work in cultural sociology has focused on national narratives, which serve as focal points for collective identification. This tradition is inspired by the classic Durkheimian insight that in order to maintain social solidarity, collectivities must engage in ritualistic practices that imbue shared symbols with moral meaning. Thus, studies have paid particular attention to ritualistic events such as parades, concerts, festivals, and sporting events

(Waldstreicher, 1997) as well as commemorative practices, such as the construction of national memorials and monuments (Collins, 2012). These empirical sites often reveal not only widely shared narratives, but also processes of contestation over the dominant interpretation of a nation's past, its core values, and its future aspirations. Once such symbolic conflicts subside, the symbols produced in the process come to serve as tacit reminders of the primacy of the nation-state in everyday life. This is as true of memorials and holidays, as it is of more banal manifestations of the nation-state, such as currency, commemorative street names, or flags waving over private homes and businesses (Billig, 1995). These ritual practices are not merely by-products of collective identification, but are essential for the reproduction of the national community.

Survey-Based Studies of Everyday Nationalism

One of the key insights of interpretive research on national identification is that the meaning of the nation-state is not uniform across a national population. Case studies of specific commemorative conflicts, however, are unable to map the full variation of national beliefs and determine their association with other social and political attitudes and behaviors. This task is more appropriately handled with survey data that enable population-level inferences based on representative samples of respondents. Most of this work has relied on a handful of multiple-wave, representative-sample surveys systematically administered across a wide range of countries.

Survey researchers face a considerable challenge, however, in operationalizing nationalism in a way that makes it amenable to quantitative analysis. This task has proven even more difficult, given the general lack of consensus in the literature about what nationalism actually entails. In an effort to organize the varied survey-based literature, we identify four ways of defining nationalism: as national attachment; national identity; national pride; and national hubris. In our view, these four labels represent different aspects of a single overarching phenomenon: the repertoire of meanings attached to the nation-state, through which modern-day nationalism maintains its hegemonic status. Under certain circumstances, these meanings also drive political change, although typically within the largely unquestioned auspices of the nation-state.

National attachment refers to identification with the nation over and above other collective entities. Social identity theorists have long argued that individuals possess multiple identities that are shaped and reproduced by institutions (Stryker and Burke, 2000). The salience of particular identities varies over time for any given individuals but it is also likely to vary, on average, across individuals. Given that the former is notoriously difficult to study outside of the laboratory setting, most scholars interested in national attachment focus on the latter, typically using basic survey questions that explicitly ask respondents about the absolute or relative importance of the nation in their lives (e.g., "How close do you feel to America?").

Some scholars view national attachment as a particularly useful measure of nationalism, because it is largely devoid of ideological content: whether a nation is important for an individual tells us little about the meanings that the individual ascribes to the nation (Huddy and Khatib, 2007). Furthermore, national attachment is related to but distinct from other concepts of interest to nationalism scholars, such as attitudes toward minorities, sentiments toward state institutions, and feelings of national superiority.

Studies have demonstrated that heightened national attachment is systematically associated with measures of political knowledge and participation (Huddy and Khatib, 2007) and prosocial behavior (Rahn, 2000). At the same time, greater attachment can activate ethnic forms of national identity, thereby promoting animosity toward minority groups (Sidanius et al., 1997). The nature of the relationship between national attachment and antipathy toward perceived out-groups often depends on how a particular issue is framed in public discourse. A national crisis, such as 9/11, can raise the relative salience of the nation in people's identity hierarchies, but whether the same occurs for ethnic identities depends on whether the narratives that mediate people's interpretation of collective events are framed in ethnically essentialist terms (Li and Brewer, 2004).

Ethnic identities, however, are only one form of collective affiliation with which national attachment interacts; people are simultaneously members of local, national, and in some cases, supranational communities, and these collective affinities often exhibit mutual complementarities and contradictions. Indeed, given the growing importance of subnational and transnational communities in the era of globalization, such place-based identities have become increasingly complex and multifaceted. Much of the research on these multilayered identification processes has been conducted within the context of the European Union (EU), the largest supranational integration project in recent history. For many years, the consensus in the EU literature has been that European and national identities are inherently opposed and that full European cultural integration depends on the gradual erosion of national loyalties. Recent studies, however, have shown that the two sets of identities can coexist, and in fact often reinforce one another, particularly among educated cosmopolitan elites (Díez Medrano and Gutiérrez, 2001; Fligstein et al., 2012).

The second dimension of nationalism – national identity – consists of specific criteria of inclusion and exclusion that are seen as legitimately defining the nation's symbolic and social boundaries (Lamont and Molnár, 2002; Wimmer, 2008). This aspect of nationalism has generated considerable attention, because it is directly tied to processes of social stratification. Groups that are viewed as external to the national community are frequently denied fundamental rights and excluded from equal access to resources and opportunities. At the individual level, exclusionary conceptions of national identity are associated with anti-immigrant sentiments, as well as support for restrictive immigration policies and cultural protectionism (Ceobanu and Escandell, 2008; Schildkraut, 2003).

Scholars typically distinguish between forms of national identity based on ascriptive (ethnic) and elective (civic) traits. There is some tension, however, surrounding the analytical utility of the ethnic–civic distinction, because of its origins in research on essential national character and the persistent finding that national identity is in fact heterogeneous within countries. Scholars have employed two strategies to resolve this tension: they have used the ethnic–civic binary at the individual level – allowing for within-country variation – or they have replaced the dichotomy altogether with more nuanced typologies.

In a study emblematic of the former approach, Jones and Smith (2001) demonstrate that both civic and ethnic forms of nationalism are found within the countries in their sample, although there is some variation in the degree to which religion is valued as a criterion of national belonging (see also Citrin et al., 1990; Hjerm, 2003). Representative of the latter approach, Citrin et al. (1994) build on the ethnic–civic binary by identifying three distinct understandings of American national identity: cosmopolitan liberalism, nativism, and multiculturalism. Similarly, Schildkraut (2003, 2011) identifies four distinct varieties of national identity, which are highly predictive of individuals' policy preferences and political behavior (for a related approach at the cross-national level, see Bonikowski, 2013).

In addition to classifying conceptions of national identity, researchers have also attempted to identify the factors that affect the prevalence of these beliefs within national populations. At the individual level, respondents who hold ascriptive views of national identity tend to have lower levels of education and lower income, be more religious and older, belong to ethnic majority groups, and have resided in the country for a longer period of time (Hjerm, 2001; Jones and Smith, 2001; Kunovich, 2009; Wright, 2011a). At the national level, countries with a lower prevalence of ascriptive national identity are typically more developed, democratic, urbanized, and culturally globalized, and are characterized by greater internal ethnic differentiation (Jones and Smith, 2001; Kunovich, 2009; Green et al., 2011; but see Ariely, 2012 on globalization); they also tend to have more generous welfare state policies (Wright, 2011b).

While national identity reflects beliefs about criteria of legitimate membership in the nation, national pride refers to the affective evaluation of the nation-state. Some researchers prefer the term patriotism to distinguish this ostensibly innocuous sentiment from a more invidious nationalism. In support of this distinction, studies have found that pride in the nation-state's institutions is uncorrelated with out-group prejudice (e.g., De Figueiredo and Elkins, 2003), while others go further to argue that pride actually leads to more tolerant attitudes (Green et al., 2011). This evidence is contradicted, however, by studies that show patriotism to be linked with a variety of authoritarian attitudes (Staub, 1997). To overcome this conceptual ambiguity, Schatz et al. (1999) distinguish between 'constructive' and 'blind' patriotism and argue that blind patriots are more chauvinistic and feel more threatened by minorities, while constructive patriots have a greater sense of political efficacy (Hjerm, 1998; Parker, 2007, 2010).

In contrast to research that views national pride as unidimensional (whether positive or negative), other studies argue that national pride is itself heterogeneous and domain specific, consisting of distinct sentiments toward national institutions and the nation's cultural heritage (Hjerm, 1998; Bonikowski, 2011). Indeed, this distinction is consistent with historical research on nationalism, which has sought to understand how political units (i.e., states) come to be viewed as legitimate authorities over imagined communities of shared fate (i.e., nations). The two varieties of national pride appear to have distinct associations with other aspects of nationalism, as demonstrated by Ariely (2011): pride in the nation – what he calls "cultural patriotism" – is correlated with ethnocultural conceptions of national membership, while pride in political institutions (i.e., 'political patriotism') lends itself to civic forms of national identity.

The final dimension of nationalism prevalent in existing scholarship is national hubris – or more conventionally, chauvinism. While the other aspects of nationalism are inward oriented, hubris is concerned with judgments of the nation's position vis-à-vis the rest of the world (much as individual hubris involves perceptions of superiority to other people). For some scholars, particularly in political psychology, hubris is coterminous with nationalism as a whole, typically in juxtaposition with the ostensibly more benign patriotism.

The primary reason for the scholarly interest in national hubris is its association with support for bellicose foreign policy (Kosterman and Feshbach, 1989) and authoritarian politics (Blank, 2003). A heightened sense of national superiority logically lends itself to the belief that the nation should pursue its interests against all odds, even if this places it in conflict with others. Not surprisingly, such views go hand-in-hand with uncritical support for the state that is a hallmark of 'blind patriotism.' It is likely that the effect of hubris on aggressive policy preferences is partly mediated by general out-group antipathy, as measures of hubris are also correlated with prejudice against minority groups (Blank and Schmidt, 2003; De Figueiredo and Elkins, 2003).

Limitations and Future Directions

As this article demonstrates, research on nationalism is rich in empirical findings and, increasingly, in theoretical sophistication. The literature does, however, suffer from conceptual confusion and a tendency to conflate specific aspects of nationalism with the concept as a whole. In what follows, we identify possible areas for further theoretical and methodological elaboration that may help overcome some of these limitations.

The first step for future research is to take seriously the role of meaning-making in people's collective understandings of the nation. Drawing on insights from cultural sociology and cognitive psychology, scholars should shift their focus from specific attitudes to the relational structures of meaning that constitute collective representations of the nation. People are not merely patriots or chauvinists – their schemas of the nation are likely to combine the four dimensions of nationalism (attachment, identity, pride, and hubris) in complex webs of meaning. Mapping these cultural networks and understanding their causal role in political behavior and policy change is an important task that is beginning to be taken up by nationalism scholars (e.g., Bonikowski, 2011, 2013; Centeno and Abascal, 2012).

A second important objective for future research is to gain a better understanding of the relationship between cognitive and affective components of nationalism. Nationalism has long been understood as an ideology that evokes a complex array of emotions, such as fervent pride toward the nation-state, revulsion against perceived out-groups, or superiority compared to other national populations. Indeed, without

the deeply emotional content of nationalist beliefs, it would be difficult to explain the more extreme forms of behavior fueled by nationalist ideology, such as people's willingness to risk their lives at wartime in the name of the national community. But emotions are likely to play an important role in routine forms of nationalism as well with important consequences for political behavior and intergroup relations (Feinstein, 2013). As the empirical study of emotions becomes increasingly prevalent in cultural sociology and political sociology, the timing is opportune for a more explicit focus on affect in nationalism studies as well.

Third, nationalist beliefs need to be studied over time. For much of its development, the literature on nationalism has treated its object of study as temporally stable. This is as true in studies of country-level nationalist ideologies, where essential features of national character are presumed to date back to a given nation's founding moment, as it is in survey analyses, which implicitly view individuals' responses as indicative of their time-invariant attitudinal orientations. Yet, these stability assumptions are in tension with a growing volume of research that shows the intensity and content of nationalist ideas to change in reaction to exogenous shocks to the nation, shifts in political discourse, and life-course events. To resolve these contradictions, more work needs to be done on the dynamic aspects of nationalism and particularly on situational factors that increase the salience of national identities for individuals and collectivities (Collins, 2012).

Finally, in addition to studying nationalism itself, researchers should also gain a better understanding of the relationship between nationalism and other political belief systems. For instance, a large literature in political science and political sociology has become interested in the rise of right-wing extremism in Western European polities (Taggart, 2000; Mudde, 2007). These studies often refer to the radical parties using seemingly interchangeable labels, such as populist, nationalist, conservative, xenophobic, and anti-immigrant. It is clear that supporters of these political movements subscribe to particular conceptions of the nation-state and that the rhetoric of the movement leaders is intended to resonate with such beliefs. At the same time, however, nationalism is only one element of the multifaceted ideological strategy utilized by extreme parties. Just how nationalist concerns interact with other arguments that do not necessarily evoke the nation is an important topic for future study.

Conclusion

Despite pressures from globalization, the nation-state remains a predominant unit of political governance, cultural integration, and collective identification. Indeed, the international nation-state system is so thoroughly institutionalized that most people view it as a natural way of organizing human society. Yet, the meanings attributed to the nation vary considerably within and across country borders. Over the past two decades, scholars have begun to investigate this variation from a number of complementary perspectives. The resulting studies have produced a wide range of consistent findings about the effects of multiple aspects of nationalism on intergroup relations and public policy preferences, as well as the impact of sociodemographic and country-level predictors on nationalist attitudes. Although this work has its limitations, it has opened the way toward new approaches that can better account for the multidimensionality, dynamism, and emotional content of nationalism, as well as its ongoing interaction with other salient political ideologies. Given these developments, the future of research on contemporary nationalism looks promising.

Natural Disasters: Health-Related Aspects

Jan D Reinhardt, Institute for Disaster Management and Reconstruction of Sichuan University and Hong Kong Polytechnic University, Chengdu, Sichuan, China
James E Gosney, International Society of Physical and Rehabilitation Medicine (ISPRM), Geneva, Switzerland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Natural disasters are sudden ecological disruptions or threats exceeding the adjustment capacity of affected communities. Natural disasters impact on public health directly by causing death and traumatic injuries and indirectly through compromise of public infrastructure, disruption of health care delivery, and displacement of affected populations. Health consequences of natural disasters include fatalities, traumatic injuries, communicable disease, psychological disorders and distress, and long-term disability. Public health in disaster-affected regions can be managed with a cycle encompassing response, recovery, mitigation, and preparedness phase.

Natural disasters are sudden ecological disruptions or threats that exceed the adjustment capacity of the affected community and require external assistance (Lechat, 1979; WHO, 1980). Natural disasters can be broadly classified into categories including geophysical such as earthquakes and volcanic eruptions; hydrological such as floods; meteorological such as hurricanes; climatological such as heat and cold waves and droughts; and biological such as epidemics (Guha-Sapir et al., 2012). Natural disasters considerably impact the health of affected populations directly – by injuries sustained due to collapsing buildings in an earthquake, for example – and indirectly through compromise of public health infrastructure and services with loss of basic needs such as drinking water, nutrition, sanitation, and shelter. Health workers and officials may also be killed or displaced (WHO et al., 2011d).

Health Consequences

Public health consequences of natural disasters include mass fatalities and casualties, communicable disease, long-term physical impairments, and mental health conditions including anxiety, posttraumatic stress disorder, and depression. Preexisting chronic illnesses and disabilities may also be exacerbated.

Fatalities

From 2003 to 2013, over 1.1 million people died due to natural disasters worldwide with earthquakes accounting for more than half of fatalities (see **Figure 1**). Main causes of death vary by type of disaster and include direct causes such as trauma due to building collapse (earthquakes) or flying debris (hurricanes) and drowning (floods, hurricanes); indirect causes include motor vehicle accidents (Doocy et al., 2013a,b,c). Evidence on risk factors for mortality due to disaster is mostly inconclusive. Children, the elderly, and persons with disability are vulnerable groups (Doocy et al., 2013a,b,c; Reinhardt et al., 2011). Males have been reported to be at higher risk of death in developed countries while females are exposed to an increased risk in developing countries (Doocy et al., 2013a,b,c).

Natural disasters can result in large numbers of fatalities, which exceed the local capacity for mortuary management,

Figure 1 Absolute numbers of deaths from natural disasters by disaster type; 2003–13. Data extracted from the Centre for Research on the Epidemiology of Disasters online database EM-DAT: The International Disaster Database. http://www.emdat.be/database (accessed 02.02.14.).

necessitating mass fatality management (WHO et al., 2011c). Immediate health risks to the general public from dead bodies are often overestimated, however. Secondary health risks to injured populations, victims' families, and health care workers include injuries sustained when moving bodies or debris and psychological distress which may be exacerbated when funeral rites are delayed or not held. Diversion of health workers from treatment of living victims to management of fatalities also compromises public health in the wake of a disaster (WHO et al., 2011c).

Casualties

The number of persons injured exceeds deaths in most natural disasters and a significant increase in the ratio of injuries to deaths over time has been reported. This trend may primarily reflect advances in disaster preparedness and response (Reinhardt et al., 2011). Casualties following natural disasters are mainly due to blunt trauma, crush injuries, near drowning, and psychological sequelae (WHO et al., 2011b). Severe traumatic include fractures, spinal cord injury, and traumatic brain injuries; less-serious soft tissue injuries such as lacerations and muscle strain are common. Since survival probability from serious injury significantly decreases after 24 h, rapid extrication, on-scene stabilization, and transportation to a definitive care facility is critical to survival. Appropriate surgical and medical intervention also helps ensuring survival and preventing long-term consequences including permanent disability and mental disease (Leaning and Guha-Sapir, 2013; Li et al., 2012). Mass casualty triage, the prioritization of treatment of victims based on severity of injury, chances of survival, and long-term health prognosis, is required given limited medical resources and other health constraints in a disaster (Iserson and Moskop, 2007).

Communicable Disease

Largely misreported by the media, communicable disease transmitted by dead bodies is in fact a myth (Watson et al., 2007). The risk of infectious disease in natural disasters may be significantly increased by disrupted or nonexistent public health services and increased limited access, especially in rural areas. Lack of adequate predisaster disease surveillance and control programmes, delayed launch of post-disaster programmes, and low levels of immunity to vaccine-preventable diseases also contribute strongly. Population displacement with resulting overcrowding, lack of clean water, inadequate nutrition, and poor sanitation are a significant source of infectious disease in natural disasters. Evidence for outbreaks of communicable disease after disaster has been best documented for floods (Watson et al., 2007; WHO et al., 2011a). Communicable diseases transmitted in natural disasters are categorized in **Table 1**.

Mental Health

Psychological distress resulting from adverse health consequences, loss of home and livelihood, and death of family and friends result in a high incidence of post-traumatic stress disorder and other disaster-related mental conditions including anxiety disorders, depression, psychosis, and substance abuse in disaster populations. Persons may also experience exacerbation of preexisting conditions due to additional disaster-related distress complicated by disruption of medication and psychotherapy treatment plans as well as loss of general social support. Adequate treatment of postdisaster mental health needs is extremely challenging given often underdeveloped predisaster mental health systems, the high burden of mental disease, difficulty in establishing postdisaster programs, and the complexity of treatment plans including length of treatment time required (Jones et al., 2007; WHO, 2013a).

Long-Term Physical Disability

Long-term physical disabilities due to natural disasters are primarily related to physical impairments resulting from traumatic injuries sustained in the disaster, which have persistent or otherwise long-lasting effects. Inadequate management of other physical injuries and communicable disease as well as mental health conditions can also result in long-term physical impairments. While the focus of medical disaster response has

Table 1 Communicable disease categories associated with natural disaster

Category	*Cause*	*Examples*
Waterborne diseases	Lack of safe water, drinking contaminated water, poor sanitation, increased proximity to rats	Diarrheal disease (i.e, cholera, hepatitis A/E) Leptospirosis
Vectorborne diseases	Increased vector population (i.e, new mosquito-breeding sites due to standing water), increased risk due to weakened immunity due to malnutrition	Malaria Dengue fever Japanese encephalitis
Diseases due to crowding	Increased person-to-person transmission in overcrowded habitation sites, lack of available vaccines, increased risk due to weakened immunity due to malnutrition	Measles Neisseria meningitidis Acute respiratory infections
Other vaccine-preventable diseases	Contact with infectious agents including bacteria while lacking immunity	Tetanus Polio Diphtheria Pertussis

been mostly on surgical and primary care, chronic and preexisting disabling health conditions may lead to a larger burden of disease in the long term (WHO et al., 2011d). 'Disability' in this context indicates impairment in body structure and function and also includes limitation in daily activities and restriction in participation in society (WHO, 2001). Activities limited include functional activities of daily living such as walking, grooming, and toileting and societal restrictions compromise education, employment, and other opportunities for socialization. Significant traumatic disabling injuries include spinal cord injury, traumatic brain injury, burn injury, and extremity injuries such as amputations, bone fractures, and peripheral nerve injury (Reinhardt et al., 2011; Gosney et al., 2011). Exacerbation of existing physical impairments is commonplace in disasters as persons with disabilities are especially vulnerable (Reinhardt et al., 2011; WHO, 2013b). Characterization of long-term physical impairment following a disaster reflects the prevalence of injury type and therefore the primary mechanism of injury as well as demographic variables unique to the disaster including its severity, proximity to urban population centers, and time of occurrence. The 2010-Haiti earthquake, for example, resulted in such catastrophic mortality, morbidity, and burden of disability due to the high number of buildings collapsing in the densely congested capital city of Port-au-Prince during the workday (Gosney et al., 2013). Long-term physical impairments due to natural disasters can be minimized by early use of physical rehabilitation as demonstrated by improved positive rehabilitation outcomes and reduced preventable secondary complications for disabling injuries including spinal cord injury and amputation (WHO, 2013c; Knowlton et al., 2011; Zhang et al., 2013).

Emergency Management Cycle and Health Actions

Health consequences of natural disasters and other public health emergencies can be managed using a comprehensive emergency management model consisting of a cycle of response, recovery, mitigation, and preparation phases (**Figure 2**) (Hoyle, 2009). Management of mass fatalities and casualties, communicable disease, mental health conditions, exacerbation of preexisting conditions, and associated long-term physical impairments during each phase of the response depends on unique disaster characteristics and medical resource availability among other factors. Whereas a less severe disaster in a developed region with a strong public health infrastructure may be effectively managed with local resources only, a more severe disaster in a developing region results in a greater negative health impact on individuals and society and generally requires international assistance. Regardless of disaster context, effective management of health consequences across the disaster cycle of health action requires strong coordination and collaboration between responders and responding organizations at all levels of emergency management.

During the response phase, immediate medical management priorities include on-site triage of severe traumatic injuries with life-saving surgical and medical care provided at an appropriate level medical facility. Patients receive continuing care including

Figure 2 Disaster cycle of health action. Hoyle, J., 2009. Health care facility disaster management. In: Koenig, K., Schultz, C. (Eds.), Koenig and Schultz's Disaster Medicine Comprehensive Principles and Practices, Cambridge University Press, Cambridge, pp. 285–311. Copyright © 2010 Kristi L. Koenig and Carl H. Schultz. Reprinted with the permission of Cambridge University Press.

physical rehabilitation as needed until sufficiently stable for discharge. Outpatient treatment including proper wound care and rehabilitation is necessary to maximize functional outcomes and prevent complications. Community-based supports and services including educational, vocational, and social rehabilitation are also required to optimize patient integration into the community and resume a full, meaningful life (WHO, 2010). Routine population emergency and primary care health requirements must be concurrently addressed following the disaster as well, further complicating postdisaster health delivery. Concomitant with clinical activities focused on individual care, nonclinical health care response activities may include: assessment of evolving casualty patterns and medical resource requirements; management of patient triage, discharge, referral, and tracking systems; data collection, management and analysis; collaboration with other health care service providers; and coordination with emergency system and host health system and government managers.

During the postdisaster recovery phase, the additional health care burden of direct disaster injuries as well as the ongoing provision of routine emergency and primary care should be optimized, necessarily requiring strengthening of health care system capacities. Disaster-related communicable disease as well as mental health conditions and long-term physical impairments are also treated. Planning for future long-term physical impairment needs to reduce the total population burden of disability is critical to community recovery.

Mitigation of health consequences in disasters includes predisaster and emergency activities intended to limit the severity and number of casualties. Emergency planning for persons with disabilities must consider medication and equipment availability as well as evacuation and sheltering strategy to reduce secondary casualties in a disaster, for example (WHO, 2013b).

Disaster preparedness measures focus on improving health care and community-based rehabilitation system sustainability overall and disaster responsiveness specifically. Absence of disaster plans and policy has been shown in fact to compound earthquake severity of impact on elements of the local health care system (Bremer, 2003). Public health disaster response plans should address all major areas of health consequences aforedescribed, outline triage policies, and strategically map required human and physical resources including designated facilities for expansion/conversion to accommodate casualties. Plans should be refined through simulation exercises to maximize their efficacy during the actual disaster.

After a large scale natural disaster, usually funds are available from donations and nongovernmental organizations, governmental actors may be more open to innovations, and technological know-how is provided by national and international aid agencies. While natural disasters cause significant mortality and morbidity, they thus also provide opportunities for rethinking, rebuilding, and strengthening health systems including mental health and physical rehabilitation services, which are often less developed before the disaster occurs (WHO, 2013a; Zhang et al., 2013).

Abstract

The natural law tradition of thought about morality and jurisprudence has its roots in ancient Greek and Roman philosophy, was developed and systematized by Scholastic thinkers, particularly Thomas Aquinas, and continues to be influential to the present day. This article focuses on the central tradition of natural law thinking, outlining its basic features with particular attention to its political and legal implications as well as its relation to the social and behavioral sciences.

The natural law tradition of thought about morality and jurisprudence has its roots in ancient Greek and Roman philosophy, was developed and systematized by Scholastic thinkers, particularly Thomas Aquinas, and continues to be influential to the present day. While the concept of natural law played an important role in early modern moral and political theory, particularly in the works of Grotius, Pufendorf, Hobbes, and Locke, these thinkers' understanding of natural law represented a radical departure from the central tradition of moral and political thought that reached a high point in the work of Aquinas. This article, therefore, will focus on natural law theory within the central tradition, outlining its basic features with particular attention to its political and legal implications as well as its relation to the social and behavioral sciences.

The core of natural law theory is the view that, through rational reflection, human beings can discern principles of right action that direct us to order our wills toward integral human fulfillment, the overall well-being of all human beings as persons and communities. These principles hold universally in all times and cultures because the basic requirements of human well-being are rooted in an essentially unchanging human nature, although many concrete applications of these principles may vary with circumstances. Natural law thus includes a theory of value – a substantive account of human well-being in its various dimensions – as well as a theory of right action – moral rules and principles that guide and structure ethical decision making in concrete cases. It also involves an account of virtues understood as the habits of mind and character that reliably dispose one to choose and act in accordance with moral norms and that in themselves constitute an important aspect of human flourishing, but the focus here will be primarily on the first two aspects.

Natural Law as a Theory of Value

Natural law theories seek to provide objective and universal accounts of the basic and constitutive elements of human well-being, while at the same time recognizing that human good, although determinate, is multifaceted, thus leaving room for a diversity of good lives. What are these basic human goods or values that constitute a flourishing life? How are they identified? What is their relation to human nature? While there is dispute among natural law theorists about the precise answer to these questions, a common starting point is Question 94, Article 2 (q. 94, a. 2), of Thomas Aquinas's *Summa Theologiae*. There, Aquinas argues that the natural law has various precepts because it orders human beings toward a variety of goods that reason apprehends as intrinsically valuable, that is, as choiceworthy in themselves and not merely as means toward further ends. These goods correspond to and are perfective of the various dimensions of human nature. Because humans are bodily beings, life and health are inherent aspects of our well-being. Because we are social beings, friendship, the formation of communities, marriage, and family life all have intrinsic value for us. Because we are rational beings, our fulfillment involves the acquisition of knowledge, both practical and theoretical, including knowledge of the truth about God.

Contemporary natural law thinkers, such as Germain Grisez, John Finnis, and Joseph Boyle, have attempted to offer a fuller explanation of the nature of these basic goods, as well as a more complete list of them, since Aquinas mentions them only in passing as if by way of example, without any pretensions to an exhaustive treatment of the topic. Thus, in addition to the goods listed here, which are all more or less explicitly mentioned by Aquinas, Finnis speaks of the good of performative excellence, the goods of integrity (inner harmony among the reasoning and desiring aspects of the self) and authenticity (harmony between one's judgments and one's actions), as well as the good of harmony with God understood as the transcendent source of existence and meaning (Finnis, 2011).

There is some controversy among contemporary natural law theorists regarding how these goods are known and how they relate to human nature. Aquinas speaks of these basic goods as "those things to which man has a natural inclination" (q. 94, a. 2), leading some to claim that natural law bases moral norms on sub-rational desires inherent in human nature, thus denying the Humean fact–value distinction by implying that an *ought* can be derived from a mere *is*. This is one of the criticisms levied against natural law theories by H.L.A. Hart in *The Concept of Law*. Some contemporary natural law thinkers, such as Ralph McInerny and Alasdair MacIntyre, argue that the fact–value distinction is false and that moral norms are indeed derived from facts about human nature (MacIntyre, 1999, 2007; McInerny, 1982).

Even these accounts, however, are far from the crass naturalism of which critics like Hart accuse them, for they have a sophisticated metaphysical understanding of nature that distinguishes only certain essential aspects as normatively relevant. On this view, nature, and human nature in particular, is normative not 'as it happens to be' but 'as it could be if it realized its goal or *telos*.' And the *telos* or perfection of human nature is, ultimately, discovered by reason.

Other contemporary natural law thinkers, including Grisez, Finnis, and Boyle, accept the fact–value distinction and deny that natural law, including Aquinas's own formulation of it, runs afoul of that distinction when properly understood. For Aquinas, human nature is defined by rationality; what is most natural to human beings, in Aquinas's sense of the term 'natural,' is to act in accordance with reason. The natural inclinations to which Aquinas refers, as corresponding to the human goods to which the first principles of practical reason direct our choices, are not the inclinations of sub-rational desire but rather the inclinations of the will, a rational appetite that tends toward intelligible goods as apprehended by reason (Brock, 2005). Thus, while goods like life, knowledge, and friendship are intrinsic to the flourishing of all human beings because of the nature that we have and because they are perfective of that nature, Grisez, Finnis, and others who follow their account argue that practical reason directly grasps the choiceworthiness of these goods, rather than claim that our knowledge of what is inherently valuable for human beings is derivative of our prior understanding of anthropological facts. In other words, the choiceworthiness of these goods is grasped immediately by one who properly understands them and is not impeded in understanding by prejudice, partisanship, or some other factor (George, 1999).

On this view, the social and behavioral sciences can offer detailed descriptions of human attitudes, inclinations, and behaviors, their typical consequences, and the biological or cultural factors that typically engender them, but these descriptions in themselves cannot be the basis for value judgments. Nonetheless, the social sciences are not irrelevant to discerning the basic and constitutive aspects of human well-being. Rather, as Finnis puts it, they are helpful insofar as they offer "reminders of the range of possibly worthwhile activities and orientations" (Finnis, 2011: p. 81). And, while the mere fact of universal or near-universal agreement about a value is insufficient to establish it as such, comparative anthropology does provide evidence of broad cross-cultural and transhistorical appreciation of the values that Aquinas and contemporary natural law theorists point to as basic and constitutive forms of human well-being – as one would expect if, indeed, basic human goods are as these theorists describe them.

Natural Law as a Theory of Right Action

Recognition that goods like life, knowledge, and friendship are choiceworthy in themselves as distinctive aspects of human flourishing corresponds to what natural law thinkers call the first principles of practical reason, principles of the form 'X is to be done and pursued, and its contrary to be avoided,' where X is any one of the basic goods. They are first principles because they are the starting point for all practical reasoning, reasoning about how to choose and act. In this sense, they are analogous to the first principles of theoretical reasoning, such as the principle of noncontradiction (a thing cannot both be and not be at the same time and in the same respect), which all reasoning necessarily presupposes. These first practical principles in themselves, however, distinguish only intelligible from unintelligible (irrational) choices and actions, not morally right from morally wrong actions. Any action in pursuit of a basic good is intelligible (and, to that extent, rational) but not necessarily moral. A surgeon, for instance, might perform unnecessary operations on her patients for the sake of practicing and improving her skills. Although obviously immoral, such conduct is hardly irrational or unintelligible, as would be the conduct of someone who for no reason at all devoted his life to hopping on one foot all day in the corner of his room.

How, then, does the theory of value discussed in the section Natural Law as a Theory of Value form the basis for concrete norms that guide morally significant choice and action? As a preliminary matter, it is worth mentioning here that one of the core differences between natural law thinking in the central tradition and the natural law theories typical of the early modern and modern periods is that, in the central tradition, law's force (i.e., its binding power or obligatoriness) lies essentially in its reasonableness, rather than in the will or command of a superior – of any authority, human or divine, understood as external to reason itself. As Aquinas puts it, law is essentially an 'ordinance of reason'; its reasonableness is the source of its binding power *as law* (as opposed to brute force) (q. 90, a. 1, 4).

Thus, according to Finnis, the first and most general moral principle is "be fully reasonable," where reasonableness is understood not merely instrumentally as a matter of choosing efficient means toward pregiven ends but also, rather, as including within itself a substantive account of the ends worth choosing, of the various distinct and irreducible goods that are constitutive of human flourishing. To choose and act reasonably, then, are to choose and act in ways that respect the intrinsic value (choiceworthiness) of *all* of the basic goods for *all* human beings – that is, to choose and act in ways that are compatible with the ideal of integral human fulfillment (Finnis, 2011: p. 451).

A number of concrete moral norms flow from this master moral principle. Since, for instance, practical reason directs us toward each of the basic goods and away from their contraries, a direct choice to damage human well-being in any of its basic forms is always unreasonable, and therefore immoral – i.e., against the natural law. This norm accounts for the existence of absolute moral prohibitions that are binding always and everywhere, such as the prohibition on direct killing of innocent human beings. (Some, including Finnis, hold that this prohibition includes *all* direct killing, but all natural law thinkers agree that the natural law strictly prohibits at least direct killing of the innocent.) It is important to note here that these absolute moral prohibitions apply only to choices and actions *directly* against the basic goods, not choices that give less priority to one good rather than other, or that accept damage to one good as a foreseeable side effect of pursuing another good. Indeed, since human beings have limited time and energy, and the

basic goods are irreducibly distinct, acting for any one good necessarily means forgoing the opportunity to act for another. Choosing to spend an afternoon visiting a sick friend entails choosing not to spend that afternoon studying or going to the gym. Such a choice, however, is not *directly* against the good of knowledge or health, even if one knowingly risks catching the friend's illness by visiting.

Being fully reasonable, of course, involves constraints not only on what one may directly will or choose to do, but also on the acceptance of the foreseeable side effects of one's actions. Since each good is a distinct and, in the abstract, equally choiceworthy form of human well-being, and since each good is grasped as inherently valuable not only for oneself but for all human beings, arbitrariness in prioritizing one good over another and in favoring the well-being of one person over another is always unreasonable. Hence the moral requirement, for instance, to develop and follow a rational plan of life that takes into account one's talents, dispositions, realistic possibilities, obligations to other people, and so forth, and to establish one's priorities accordingly; hence also the moral requirement of fairness, traditionally expressed by the Golden Rule.

In part because friendship and sociability are themselves intrinsically valuable as well as instrumentally indispensable for human well-being, and in part because the basic forms of human well-being are grasped as valuable not only for oneself but for all human beings, full practical reasonableness also implies a moral requirement to favor and foster the common good of one's communities. It is important to point out here that a natural law understanding of the common good is completely different from the utilitarian notion of the greatest good (or 'happiness') for the greatest number. Indeed, on the natural law view, this utilitarian ideal is not only wrong but also incoherent, because the distinctive forms of human well-being are irreducible to one another or to any more basic value. Thus, they are in a certain sense incommensurable as they figure as options in morally significant choosing. Even if the choice to visit a sick friend rather than go to the gym is morally right, that does not mean that the goods one participates in (the good of friendship, among others) by doing so include all of the 'goodness,' and more, that one would have gained by going to the gym. There simply is no common currency in which the basic goods can be added to or subtracted from and weighed against one another, as utilitarianism would require. Nor, on the natural law view, are individual human beings fungible repositories of 'goodness' or 'utility' such that one person's good can be weighed against the good of others in a way that could justify, say, killing (i.e., intending the death of) one person in order to save 1000. Rather, according to natural law theory, the good of each individual is a constitutive element of the common good, and the common good is just the set of conditions within which all members of the community, as individuals and in association with one another, can pursue their well-being. Further, contributing to the common good is itself a constitutive element of the well-being of any individual, and in the concrete this generally means fulfilling one's particular obligations to others (as individuals and groups) to and for whom one has a particular responsibility by virtue of one's professional, social, familial, religious, and/or civic ties.

Natural Law and Human Rights

By providing (1) a substantive account of the basic and fundamental forms of human well-being, (2) moral norms that require respect for each of these basic values both in oneself and in others, and (3) a conception of the common good in which the good of each individual is a constitutive aspect, natural law theory offers a firm basis for human rights, including rights that are absolute (i.e., universal, inalienable, and inviolable), avoiding an undue proliferation of ungrounded rights claims as well as the putative antagonism between individual rights and the common good. According to natural law, the language of rights is simply a way of expressing what is right or just – that is, of expressing the requirements of justice – from the perspective of the person or group to whom something is owed. Thus, absolute rights are, on this view, simply the flip side of absolute moral prohibitions. The claim that human beings have an absolute right to life and bodily integrity (i.e., a right against being killed, maimed, or tortured as an end in itself or as a means to some end), for instance, is simply a translation into rights-language of the claim that there is an absolute duty to refrain from direct killing (or maiming) of innocent human persons. Similarly, absolute negative rights (rights that require only noninterference on the part of others) correspond to all of the basic aspects of human well-being – hence the right of association, the right to pursue one's profession, the right to marry and raise one's children, the right to practice one's religion, as well as rights of conscience more broadly. These rights are absolute insofar as they involve an absolute immunity from actions on the part of others (individuals or communities) whose object is precisely to impede one's participation in the relevant good. Further, acting in ways that *indirectly* harm others with respect to their participation in basic values – i.e., not directly intending such harm but only accepting it as a side effect – is a violation of rights insofar as there is a lack of fairness – i.e., insofar as one would not be willing to accept the harm in question if it were to fall on oneself or one's own.

For example, one implication of the right to life is the norm of noncombatant immunity in war. Governments can run afoul of this norm – and thus violate human rights – not only by *directly* targeting noncombatants but also by a lack of fairness in their willingness to accept noncombatant deaths as a side effect of attacks on legitimate military targets. Such a lack of fairness would be involved if, for instance, the government were to order a daytime attack on a munitions factory located next door to an elementary school, when it would refrain from such an attack if, instead of the factory being located near an elementary school, it were located near a prisoner-of-war camp. In other words, the government would be acting unfairly by treating the lives of 'enemy' children as much less important than those of its own soldiers being held prisoner.

Natural law also provides the basis for so-called 'positive' rights, rights that are not simply immunities but that involve a claim of entitlement to receive certain benefits or services from others. Given the understanding of human well-being that is essential to natural law theory, as well as natural law theory's view of human beings as naturally social due in part to human interdependence and vulnerability, it makes sense to speak of human rights in regard to goods like healthcare, adequate food

and shelter, education, and so on. Yet such positive rights are much more indeterminate than negative rights. While negative rights involve a clear claim on *everyone* to refrain from violating the right in question, to make positive rights meaningful it is necessary to specify precisely *who* has the obligation to provide the benefits or services in question, and precisely *how* to do so, and these questions cannot be answered in the abstract, for they will vary depending on social, cultural, political, and legal factors, as well as individual circumstances. The principles of natural law thus leave much room here for prudential judgment on the part of both individuals and political authorities.

Natural Law and Authority

Natural law theories also offer an account of legitimate authority and of the obligation to obey the law that avoids some of the well-known and seemingly intractable difficulties of basing legitimate authority on actual or hypothetical consent. Beginning with early modern social contract theorists such as Pufendorf, Hobbes, and Locke and continuing into the contemporary period, most famously with the hypothetical contract theory proposed by John Rawls in a *Theory of Justice*, there is an assumption that to be a part of an authoritative community – a community with some degree of decision-making power over its members – is, although ultimately necessary for survival and well-being, fundamentally unnatural to human beings. For authoritative communities to exist legitimately (rather than merely on the basis of brute force), they must be based upon the consent of their members, who are understood as free and equal individuals subject to no preconsensual authority structures.

By contrast, natural law theories within the central tradition view human beings as naturally enmeshed within a web of authoritative communities at different levels – the family, religious communities, fraternal and civic associations, and the political community – whose legitimacy is not based primarily on consent but on their inherent connection to the common good, which natural law requires each individual to protect and promote. On the natural law view, justifying political authority is not fundamentally a matter of consent but, rather, of recognizing that solving coordination problems among individuals, families, and particular associations is necessary for the common good, and that the only practicable way to solve such problems is through authority. This would be true, on the natural law view, even in a society of saints, because the practical problems involved in coordinating to pursue common aims admit many reasonable solutions. What practical reasonableness requires is only that *one* of the many possible solutions be adopted and followed by all, and this can be done only if authority is established (be it a person, a group, or a particular decision-making procedure such as majority vote). Thus, reason requires obedience to authority insofar as that authority is on balance actually helping to solve coordination problems in view of the common good and has not degenerated into tyranny. Consent, on this account, need not be a part of the justification of authority at all. All that is necessary to generate an obligation to obey political authority (or any authority) is the recognition that such authority is in fact conducive to the common good.

Natural Law and Positive Law

It is a famous natural law dictum, articulated by Augustine and reiterated by Aquinas, that "an unjust law is no law at all." Legal positivists, including H.L.A. Hart, have harshly criticized this view, arguing that law is simply a matter of social fact and that laws have no necessary connection to morality, because patently unjust laws clearly can and do function as laws insofar as they are accepted as law and treated as binding by both officials and community members (Hart, 2012). Yet the natural law claim that an unjust law is no law at all does not conflict with the claim that, as a matter of social fact, unjust rules do function as laws. Nor does the natural law view deny that there is value in providing a purely descriptive sociological account (as Hart himself proposes to do) of what it means for a particular social rule to function as a law. The natural law theorists' claim, rather, is that the unjust social rule that recognizably functions as a law is not a law in the fullest – i.e., moral – sense of the term, and thus that it is possible to criticize that law as failing precisely to fulfill the justifying purpose of law as such (i.e., as failing to advance the common good, in part by not establishing a fair balance of benefits and burdens among the community's members) (George, 2007).

According to the natural law view, a positive law is just to the extent that it is in accordance with the natural law. This does not mean, however, that positive laws are simply straightforward deductions from the natural law, that the positivity of a law adds nothing to its moral force, or that the positing of a law cannot sometimes itself create moral obligation where it would not otherwise exist. With regard to the mode of their derivation from natural law, positive laws can be divided into two categories. The first category consists of positive laws that flow directly from the requirements of natural law, such as laws against murder. The second category consists of positive laws that relate more indirectly to natural law by way of what Aquinas calls the 'determinations' of the legislator. As Aquinas explains, such laws are derived from natural law not, as opposed to those in the first category, like "conclusions deduced from general principles," but like "implementations [*determinationes*] of general directives" (q. 95, a. 2). Thus, for instance, natural law requires that some resources be pooled for the sake of public goods such as bridges and roads, but natural law does not indicate any specific way of doing this. Indeed, the prudent legislator will take into account the particular social and cultural conditions of the community in an attempt to devise the most just and expedient means of pooling resources. What results – a set of tax laws, for instance – is a determination or specification of the natural law requirement to favor and foster the common good (in this case, through the contribution of material resources) that is binding only for the members of a particular community. In this sense, such laws are binding entirely because they are posited, even though ultimately their normative force comes from the permanent principles of practical reason. The choice (determinatio) of rulers will thus determine what is uniquely just for those under their rule.

Precisely because the normative force of all laws ultimately flows from their relationship to the requirements of natural law, laws fail *as laws* to the extent that they are in conflict with the requirements of natural law. Hence the claim that an unjust law is not law in the full moral sense of the term, even though it

may indisputably function as such as a matter of social fact. According to Thomas Aquinas in the *Summa Theologiae* (q. 96, a. 4), there are several ways in which laws can be unjust. The first is procedural: laws can be unjust if they are not enacted in accordance with the established decision-making procedures or go beyond the limits of the lawmaker's rightful authority. Laws can also be unjust on substantive grounds in two ways. First, they can directly contradict the natural law, as did genocidal laws in Nazi Germany or laws maintaining the institution of slavery in the pre–Civil War United States. Second, they can fail to fairly distribute the benefits and burdens of common life. Note that established decision-making procedures themselves can also be substantively unjust on grounds of fairness.

A famous application of this understanding of the proper relationship between natural law and positive law is found in Martin Luther King's 'Letter from a Birmingham Jail,' in which he defends his acts of civil disobedience against those who criticize him for failing to show sufficient respect for the law (King, 1963). Citing Thomas Aquinas, King states that "an unjust law is a human law that is not rooted in eternal law and natural law." Glossing this in a way that highlights the inherent connection between natural law and human flourishing, and paralleling the connection that should exist between positive law and the common good, King writes, "Any law that uplifts human personality is just. Any law that degrades human personality is unjust". He then goes on to point out the obvious truth that segregation laws are a clear instance of the latter, and thus are unjust and do not merit respect as laws. Aside from his criticism of segregation laws as directly contradicting the natural law, King also points to lack of fairness as an independent ground for the injustice of segregation laws: "An unjust law is a code that a numerical or power majority group compels a minority group to obey but does not make binding on itself." He argues further that the laws in question are procedurally unfair because "devious methods are used to prevent Negroes from becoming registered voters." In other words, King makes a comprehensive case that the laws against which he is protesting are truly not laws at all in the morally relevant sense because they violate all of the criteria, both substantive and procedural, for just laws.

Yet King also follows Aquinas and the natural law tradition more broadly in recognizing that, even when faced with patently unjust laws that cannot be obeyed in good conscience, respect for the system of law as a whole (provided the system is not completely corrupt) – and thus for legitimate authority as conducive on the whole to the common good – must nonetheless be maintained. That is why King stipulates that "one who breaks an unjust law must do so openly, lovingly, and with a willingness to accept the penalty." He thus distinguishes himself from the anarchist by arguing that his acts of civil disobedience – in which he openly defies a patently unjust law and accepts imprisonment for doing so, with the aim of "[arousing] the conscience of the community over its injustice" – are "in reality expressing the highest respect for the law." Only because he holds this view of positive law as deriving its binding character *as law* (as opposed to brute force) from its essential relationship to the natural law can King make such a claim.

Indeed, at the heart of the natural law tradition's criticism of legal positivism is the argument that, by denying any essential connection between law and morality (between positive law and natural law), legal positivists make it ultimately impossible to distinguish law from brute force, or to distinguish the civil disobedience of someone like King from mere anarchism (Simon, 1965). Further, as Hart points out, any sophisticated sociological understanding of law must be able to account for the fact that those who administer and are subject to laws view them as essentially different from mere commands backed by threats of force. By conceiving of law as inherently aimed at the common good and as having normative force precisely insofar as it achieves this purpose, natural law theorists claim to offer a more accurate description of law as social fact, as well as to provide broader moral standards according to which the justice of any particular law or legal system can be critically assessed.

Natural law reasoning has been applied to contemporary controversies ranging from bioethical issues like abortion (Kaczor, 2011; Lee and George, 2009), euthanasia (Keown, 2002), and embryonic stem cell research (George and Tollefsen, 2008) to marriage policy (Girgis et al., 2012), capital punishment (Grisez, 1970), torture (Tollefsen, 2008), nuclear deterrence (Finnis et al., 1987), and property and welfare rights (Boyle, 2001).

Naturalism

Abstract

Naturalism is a deep trend in philosophy, rather than a precise doctrine, with multiple connections in many areas of science and culture. Its starting point is the belief that nothing exists outside nature. It has been developed throughout history along two main directions. Ordinary naturalism relies on commonsense and everyday human practices to uncover reality, while scientific naturalism, dominant today, takes nature to be what physics tells us exists, and natural science to be the sole provider of genuine knowledge. Cognitive science and evolutionary biology attempt to account for mental and social phenomena in naturalistic terms.

Naturalism

Naturalism is such a protean concept that calling it a doctrine is already committing a Procustean reduction. A bewildering array of philosophers and philosophies are regarded, or consider themselves as exemplifying naturalism, with hardly any further commonality, or so it seems, between them. Yet naturalism is also sharp enough an indicator that just about anyone in philosophy or in the sciences of man is sensitive to the naturalistic valence of whatever theory, author, approach they happen to be confronted with. Many authors see it as so vague and equivocal as to be essentially useless; yet the same authors use the term in their own productions. This need not be an inconsistency: in context, naturalism may take on a meaning precise enough for theoretical purposes. Still, there is a peculiar versatility of the term, which is often obfuscated in expositions that focus right away on a certain situated understanding, and give no indication of there being other meanings, deemed just as central in different contexts. Nor is this versatility a mere accident: the issue of naturalism is inescapable and brings out an indefinite range of responses from thinkers in philosophy and the sciences of man from all walks of academic life.

At the highest level of generality, naturalism is a stance; the stance leads to one of two broad heuristic principles; each of these eventuates in any one of a large variety of doctrines, which in turn range from abstract speculations to well-articulated research programs. This article will focus on what happens to be, in the present intellectual mood, the most salient variety of naturalism, viz. scientific naturalism, seen as a cohesive set of theoretical commitments giving rise to, and getting support from, a cohesive set of research programs in philosophy and the sciences of man (which are taken here to include the social sciences). But first the broader landscape will be briefly sketched; it is the proper background against which the major positions are being debated and will continue to be in the foreseeable future, as the present dominance of scientific naturalism is increasingly contested while the research programs that it inspires and that support it show no sign of weakening.

Naturalism in General: One Stance, Two Branches, Three Positions

As a stance, naturalism presents a united front. To adhere to naturalism, one must, first, believe or be willing to bet that nothing exists outside of nature and grant that conjecture a central position among one's theoretical commitments; second, have the courage to rebel against received views; third, to have at least a conjecture regarding how to pursue the goal of showing that nature exhausts reality. Naturalists are rebels because at all times, in one or another realm of thought, the received view promotes some form of dualism, one branch of which escapes nature – as if the struggle to establish the unity of reality were never definitively won.

Of course, both nature and reality are contentious concepts, and to equate the two is merely the starting point of a reflection which branches out in many directions. Still, one thought that is common to all forms of naturalism is this: only by looking at nature, at what surrounds us and stretches under our eyes, can one ascertain what actually exists. It is a metaphor for sure, and the central difficulty emerges as one tries to cash out the visual element. Nature is not antecedently given: it is gradually revealed to the inquiring subject. The naturalist seems faced with a dilemma. Either she claims to know what inquiry is, or she does not. If she does, she has a conceptual grasp on nature, as that which inquiry gradually reveals, but she has already forsaken naturalism: inquiry is not 'visible' in any extended sense, so her knowledge must stem from, or belong to another realm. If she does not, she has no conceptual grasp on nature, because whatever nature is, it includes both visible or more broadly perceptively salient things, but not all such things, as well as a wealth of nonperceptively salient things, and only inquiry can sort all existing things from the rest. But without an epistemic grasp on nature, it is hard to see what sense can be made of the claim that nature is all that exists.

There is a way out of the dilemma, championed by Quine (1969). The naturalist does not start from scratch: she has a pretty secure hold on parts of nature, and she is acquainted with some procedures of inquiry. The way to go then is to lean on the means of inquiry one already possesses and trusts in order to broaden one's knowledge of nature, and to lean on one's broadened understanding of nature in order to augment

one's understanding and means of inquiry. Success of this bootstrapping strategy is not guaranteed. In fact, it may be argued that it rests on a postulate of continuity: what we do not yet know must in some way resemble what we do know, as it is our present means of inquiry that are to reveal it, and by the same token, the new means of inquiry must in some sense be continuous with those we already have. The continuity postulate sits well with naturalism, which favors unity and connectedness over all forms of essential duality. And it clashes with some received views: of nature as composed of semi-independent orders, and (more starkly) as inquiry evolving by leaps, under the combined effect of criticism, whereby a method of inquiry abruptly appears as unacceptable, dragging in its fall entire patches of previously held beliefs about nature, and of creative thought, bringing into being novel means of inquiry that in turn disclose unsuspected areas of nature.

It is customary to distinguish ontological from methodological naturalism: the former (sometimes called metaphysical naturalism) is a claim on what (actually) exists, as above, the latter (also sometimes called epistemic naturalism) a claim concerning the (legitimate) way of getting to know reality. As we have just seen, the issues of reality and of inquiry are intertwined; yet it is possible to consider them separately. The possibility arises once a starting point for the bootstrapping process has been chosen. And this is where a major parting of the ways occurs. The crucial question is: Where do we seek guidance as we start off? There are two plausible answers: commonsense or everyday experience, on the one hand, science on the other. Each of these operates as a heuristic. Neither uniquely determines a research program, a theory, or a doctrine. Rather, they orient our thinking in one or the other direction.

When the starting point is the natural stance toward the world and the human experience, consisting in mankind's shared perceptual faculties, cognitive resources, linguistic, and other practices, the heuristic is what might be called ordinary naturalism. An early representative is Thomas Reid, who based his well-known commonsense naturalism, opposed to Hume's, on a conception of commonsense as epistemically privileged. But as a general orientation this kind of naturalism need not be dependent on a Reidian view of commonsense, and focus instead on practice and/or language. It accommodates a wide variety of philosophers, often but not systematically linked to pragmatism or ordinary-language philosophy, from Goethe and Nietzsche to Wittgenstein and W. Sellars, and exemplified today by such authors as Huw Price, John McDowell, Robert Brandom, perhaps Thomas Nagel, and others (see De Caro and Macarthur, 2004).

What those thinkers have in common are their reservations with respect to the other main branch of naturalism, dominant today. More cannot be said in this article. The focus from now on will be that other branch, scientific naturalism. Not that ordinary naturalism lacks relevance for the sciences of man. But its main contributions are critical and foundational: it is in part a rebellion against the excesses of a higher-order dichotomy, one that pits natural science against other forms of understanding. First-order research programs pursued today are overwhelmingly on the side of scientific naturalism, and a large part of contemporary debates concern the value and scope of these proposals.

Scientific naturalism is the heuristic that recommends that the bootstrapping process start with the current natural science as method of inquiry, and natural-scientific knowledge as knowledge base. Ontological (scientific) naturalism claims that all that exists is that whose existence is granted by the natural sciences; methodological (scientific) naturalism claims that natural science is the sole reliable method of inquiry regarding the realm of existing things (for a classic and detailed exposition, see Papineau, 1993).

As remarked earlier, the ontological and methodological claims may seem to be two sides of the same coin, and indeed that is how they are viewed by many of their proponents, be it of the 'ordinary' or scientific persuasion. But as announced, they can be pursued separately, once the starting point of the bootstrap has been fixed. So, for example, someone might be convinced that natural science provides the only access to genuine knowledge without taking a stand on what exists and how that might be determined. And someone may be wedded to the thought that natural science is the arbiter of existence, but be indifferent to the means of access to truth (except of course regarding existence). Indeed, indifference may turn into rejection: the first thinker might actually affirm the existence of a realm unverified and unverifiable by natural science (and thus not susceptible of genuine knowledge), or simply deny that the issue makes sense; similarly, the second thinker might recognize sources of genuine knowledge other than natural science. Parallel possibilities arise for ordinary naturalists.

The 'ordinary' naturalist and the scientific naturalist need not disagree on all counts. The former is willing to accept natural science and its pronouncements regarding some phenomenon as long as they do not clash too sharply with the common view. The latter, in such cases, will accept the common view as an approximation of the correct view procured by science; even in the case of a serious clash, she will try to account for the existence and persistence of the common view. But she will not hesitate to reject it in favor of the current scientific view. The commonsense naturalist, absent a decisive argument against the common view, will treat the scientific naturalist's insistence on granting epistemic priority to the scientific view *also in a contested case* as a *reductio*, showing that natural science has exceeded its scope and that scientific naturalism has turned into scientism.

Among the contested cases are the usual suspects: mind, thought, meaning, consciousness, self, numbers and other abstract objects, norms, culture, practices, language, history, and so on. These are generally regarded as the bones of contention between naturalists and antinaturalists. It might be thought then that ordinary naturalists, reticent as they are to unquestionably accept the authority of natural science, are actually antinaturalists. This need not be the case. Ordinary naturalists mean to preserve naturalism against what they see as the scientific naturalists' mistake of, so to speak, putting all of one's eggs in the scientific basket; while antinaturalists see the whole enterprise as deeply misguided. To be sure, it is often a fine line separating the two groups. The situation is clarified somewhat with the introduction of a new category, one which includes ordinary naturalists next to thinkers who, like them, share a naturalist commitment and believe that the scientific naturalist overstates science's case, but do not necessarily espouse a well-articulated brand of ordinary naturalism. At this

point the various heuristics and orientations must solidify into more precise doctrines, on pain of confusion. The present state of the field is then best characterized as structured around three clusters of positions: 'liberal' or 'broad' naturalism, scientific naturalism, and antinaturalism, with the first standing somewhere between the other two.

Scientific Naturalism

Scientific naturalism ('scientific' will henceforth be omitted), in a nutshell, relies on science, and science alone, to provide a correct fundamental understanding of reality. Science is to be understood as the set of disciplines modeled after the natural sciences as we know them. Physics plays a dual role here: it is the paradigm of natural science, it also serves, in some versions of the doctrine, as the basic science in a reductive sense. However the life sciences, chemistry, and other so-called special sciences such as geology or meteorology are regarded as legitimate providers, whether or not physics is thought to be able in principle to reconstruct their findings. In practice, a vast majority of naturalistic programs would not get off the ground were it not acceptable, from the naturalist's standpoint, to take biology as an alternative model, next to physics. In fact, the main, though not the only reason why the issue of naturalism is notably different today than it was at the beginning of the twentieth century is the rise of biology: on the one hand, it now stands on equal footing with physics as a respectable science, and on the other it is much more hospitable to a natural science of man.

As indicated above, there are two sides to naturalism. Ontological naturalism concerns the 'furniture' – the constituents – of the world. Methodological naturalism concerns the legitimate ways of bringing to light the make-up of reality.

It might appear that ontological naturalism simply follows from methodological naturalism: after all, whether something is or is not part of the world is one question among many that can be asked regarding reality. But it is a very special kind of question, one which requires an answer before science can start working on the answer: science needs to know what to examine, or where to look, in order to get going. As it progresses, it revises its initial ontological commitments and in the fullness of time delivers a (fallible) pronouncement. But that result seems to depend on the starting point, the choice of which calls for a separate examination. This is one reason why ontological naturalism is a semiautonomous debate, and one which, in contradistinction with methodological naturalism, concerns mostly philosophers.

The path leading from the historical starting point of ontological naturalism to the ontological commitments of contemporary natural science is complex, and cannot be sketched here. At this point in history, according to the best-developed version of ontological naturalism, physicalism, the reconstructed starting point is this: existing entities are those located in space and time that can exert a causal influence on, or as some authors put it make a causal difference for (other) existing entities. As for the end result, the main proposal is that physics delivers the ultimate ontological judgments. In other words, there exist only entities expressly warranted by physics or made up of such entities. The main argument in favor of this starting point is the causal closure of the physical world: as our understanding of the material world has progressed, the likelihood of a case where part of the physical world would be affected by a nonphysical factor has become vanishingly small (Papineau, 1993). Moreover, if our epistemic capacity itself is natural, resulting from processes that we can account for in naturalistic terms, then in particular we can only get acquainted with entities that can have a causal impact on our cognitive apparatus. Again, there is a circle, but a virtuous one according to the naturalist: as our understanding of mind and brain progresses, the natural-causal picture of cognition becomes clearer and more persuasive, and that in turn strengthens the naturalistic premise and its conclusion.

How then do prima facie nonphysical things fit in the physicalist's world? The answer varies according, first, to the kind of thing under consideration, and, second, to the kind of naturalism one espouses. Things, on the one hand, can be entities, properties, or facts; on the other, they may belong to various realms: supernatural (in a sense whose paradigm are deities, spirits, occult forces, or principles, and so on), mental, abstract, normative, social, and so on. Entities can variously be eliminated altogether (naturalists, also of the liberal persuasion, are unanimous in eliminating supernatural entities; for example, some, but not all, scientific naturalists eliminate entities attested by folk psychology, such as beliefs or values), or else be shown to be identical to natural entities (for example, a mental state – believing that 7 is a prime number – might be shown to be identical to a state of the brain, or a family of such states; Wall Street culture in the 2010s might be shown to be identical to an evolving network including mental representations in members of a population and public representations including texts, images, tools, practices). Properties might be shown to be natural properties, either basic properties (on the model of water being identical to the natural kind of molecular composition H_2O) or disjunctions of such properties (on the model of a corkscrew being identical to one of a number of mechanical devices); alternatively, they may be shown to *supervene* on natural properties, in such a way that two entities with the exact same natural properties cannot differ with respect to the property under consideration: just as it stands to reason that two physically identical faces cannot differ in their degree of beauty, the proposal is that if one state of the brain, say, underlies resentment, another state of the brain identical, neuron for neuron so to speak, to the first cannot but underlie resentment (while resentment, on the other hand, might have nonidentical realizations as brain states). Finally, facts can be either identified, empirically, with natural facts (a ghostly apparition, for example, might be identified with a certain visual effect produced by the interaction of a natural scene and the witness, or the experience of anger with a rush of adrenalin, or again a reasoning episode with a brain process amounting to some manipulation of material symbols); or they can be seen as nonfacts, either destined for the dustbin of science (the destruction of Troy did not result from Olympian rivalries; people do not succeed because they were born under a lucky star; things do not burn by losing their phlogiston), or reinterpreted (as when the putative moral fact that killing is wrong is regarded as expressing a repugnance toward killing).

Physicalism raises several objections, four of which will be mentioned. (1) Some argue that it is not true to the facts: some entities, despite being assemblies of physical entities obeying

physical laws, exhibit 'emergent' properties, and thus deserve a place of their own in the natural ontology. The fallback is a nonphysicalist, or pluralistic naturalism, which postulates a disjunctive ontology usually comprising the ontologies of the physical and life sciences. But why stop there, it then may be asked? Why not include the ontology of the sciences of man, and take on board their load of prima facie 'suspect' entities, thus all but depriving naturalism of its substance? (2) Physicalism is charged with indeterminacy, on two grounds. (2a) Hempel's dilemma (Hempel, 1980) concerns the physics we take as our ontological guide. If we mean today's physics, we run the risk of having to change our ontology next time physics undergoes a revolution; this is a particularly worrisome prospect for those interested in the mind–body problem: all our present attempts to integrate the mind into today's physical ontology could turn out to be worthless, if, for example, quantum mechanics and cosmology were absorbed tomorrow into a totally novel theory of everything. If on the other hand we mean to refer to the ontology of physics as it will turn out in the fullness of time, then we are referring to nothing at all: who knows what that ontology will even remotely look like? One response to Hempel's dilemma is to throw in doubt the likelihood of such a revolution, and to take the bet that the present attempts to 'physicalize' the mind will not be overthrown by some fanciful sea change in physics (Bokulish, 2011). Another response goes by the name of via *negativa*: the basic intuition driving physicalism is that nonphysical entities have no place in the world as we know it (this is what two or three millennia of experiencing and experimenting seem to have taught us). We know what the main categories of prima facie nonphysical entities are: the supernatural, the spiritual, the mental, the abstract, the normative, the social, and so on. So let us rephrase physicalism as stating that the world consists solely of the nonmental, nonsupernatural, and so on, and that this latter domain is causally closed (Montera and Papineau, 2005). It is not clear that this move strengthens the case of physicalism, which seems to boil down to a conviction, based on the history of natural science, that there is no need for mental (or supernatural, and so on) stuff to account for the workings of the natural world, and that seems to beg the question. (2b) Physicalism seems to rest on an unanalyzed notion of causality, while there is at present little consensus on how causality is to be understood, and how it fits in the picture of fundamental physics, which is often said to be acausal. (3) Finally, the supervenience strategy for fastening 'suspect' entities onto the natural world, while avoiding the pitfalls of reductionism, is too weak a foundation for a full-blooded naturalism, one that would put the 'suspect' entities on the same footing as the regular ones, making them in particular susceptible to the same kind of direct control.

Methodological naturalism stands on firmer ground. First, it is relatively well defined: although there is no agreed upon set of criteria for methods acceptable in the natural sciences, there is little dispute about concrete cases: scientists and philosophers alike are generally in agreement regarding a given natural-scientific procedure – when they see one they know one. Second, it escapes the analog of Hempel's dilemma. On the one hand, methods condoned by the natural sciences are an open-ended, evolving collection, so that there is no danger of the claim dissolving whenever a new method (such as sophisticated software applied to colossal quantities of automatically generated data) comes into force. Nor does this open-endedness make the claim vague: natural-scientific methods form a well-structured set whose elements bear a strong family resemblance, and which moreover strongly support one another; no new member is admitted without having been thoroughly tested. Third, in strong contrast with ontological naturalism, methodological naturalism is, so to speak, self-referentially closed: it claims that only natural-scientific methods should be used, and it applies that demand to itself, insofar as the decision whether or not to accept a candidate method is left entirely to natural science, with no help from outside sources except perhaps philosophy, which naturalists accept only insofar as it is continuous with natural science. Fourth, is does not give any specific discipline pride of place: physics plays no privileged role, so that methodological naturalism need not impose on inquiry the unreasonable demand of conforming to physics. Finally, the demand it does make is rather clear: naturalism is *opposed* to methodologies frequently and sometimes exclusively used today in many branches of these disciplines. Only methodologies that are clearly similar to, or continuous with those used in the natural sciences, are deemed acceptable. This is not to deny that the sciences of man have their proprietary domain, or to call for the elimination of their entities and phenomena in favor of neurons, cells, molecules, or bosons. The demand rather is that no special treatment be granted to those entities and phenomena except as motivated for precise reasons and to a limited extent. The mere fact that they are attached to human beings or to human populations does not qualify them for special treatment. Cells and organisms are different from stones and cascades, yet to the extent that they give rise, in science, to domain-specific methods and concepts, that is not due to an initial decision from which the inquiry proceeds; on the contrary, it is a consequence of that inquiry, operating under the ground rules of natural science. The same goes, according to naturalism, for human beings, minds, cultures, societies: they start out as generic entities, and as the inquiry progressively identifies some of their specific features, the necessary adjustments are made, without in any way relaxing the standards of natural science. This requirement is known as the 'unity of science,' which is not (contrary to popular views) a call for reduction to physics (although some authors have indeed hoped to accomplish this ideal via a reduction of all science, regardless of subject matter, to physics) or to biology (a more popular orientation today). Naturalism, seen in this light, is simply the rejection of a specific duality, that between the natural sciences and the sciences of man, very much ingrained to this day in mainstream academic culture, despite the best efforts of naturalists over the last half-century.

In What Ways Does Scientific Naturalism Make a Difference?

That (scientific) naturalism should make a large difference is intuitively obvious. Yet there are both a variety of ways in which it does, and ways in which it does not. Naturalism makes a difference on at least five distinct issues, only one of which is directly relevant to the present volume.

The first is the existence of supernatural entities, the most prominent of which in our culture is God: naturalism sides

with atheism, and this makes a difference for theists. Yet even theists, when they put on their scientific goggles, fall back on a special kind of methodological naturalism, one which recommends the scientific stance in the daily conduct of one's scientific life: the scientist who believes in God brackets her religious beliefs when she acts as a scientist. This extends to a vast majority of philosophers, as Barry Stroud has emphasized, regardless of the fact that nonbelievers are far from constituting a vast majority among philosophers. It has long been clear that God could well have chosen to proceed precisely by those means that science can identify, and that, until recently, the (in)existence of God made a difference at most in areas where science happens to be silent – a situation which is undergoing rapid, though not necessarily lasting changes, with some radical naturalists' attempts to refute theism (Harris, 2004; Dawkins, 2006; Dennett, 2006).

The second is the quest for the ultimate reality: what are the fundamental components of the world? This is of concern to a small contingent of philosophers and physicists. Naturalism, which claims exclusive authority for natural science on this issue, and attempts to draw conclusions from the present state of fundamental physics, makes little or no difference in most other contexts, whether academic or not.

The third is the role of science in knowledge. Naturalists (of the scientific branch of course) claim an epistemic privilege for science. The weak form of the claim is that wherever science has a say, what it says has final authority, superseding all other beliefs on the same topic. The strong form is that science has 'universal coverage': anything that can be known at all can only be known by science. The weak form is relevant in contexts where rationalism is challenged: it is not an issue *within* the rationalist camp, which includes all scientists and most philosophers. The strong form is solely of philosophical import: many things are at present unknown by science, so the claim is that we are left right now in a situation of total ignorance regarding those things, which cuts no ice for those who, unlike philosophers, are not preoccupied by the issue of what counts as genuine knowledge. Both the weak and the strong forms of the claim leave us with the more pressing demand of drawing the right distinctions within the extensive set of things unknown to science, that the naturalist labels nonknowledge: those of which we have a certain kind of grasp, those which we can conceive but are uncertain about, those which we cannot conceive with any clarity, or at all, those about which we are wrong, etc.

The fourth is the nature of philosophy: here naturalism takes the form of another 'continuity thesis,' according to which philosophy is continuous with natural sciences: it shares or should share their goal, which is to acquire an understanding of the world, it aims or should aim at taking on board the lessons of science, both its results and its methods, and it does not or should not avail itself of anything like a philosophical method differing in essence from the scientific method. Insofar as philosophy remains distinct from any given science, it is due, in the naturalist's perspective, to the kind of question that it asks: too general, or too imprecise at the present stage, to be taken on by any research program in one of the established sciences.

Closely linked to this view of philosophy is the naturalistic turn in epistemology. In a seminal article, Quine (1969) defended the view that knowledge is a natural process, the output of human cognitive activities, which transform sensory stimulations into a certain kind of theoretical output. The externalist conception of knowledge sharpens this insight by attributing the difference between mere belief and genuine knowledge to the reliability of the natural processes leading to the formation of a given thought (Ramsey, 1931; Goldman, 1967).

Naturalism in this sense (sometimes also called methodological) is of direct concern only to philosophers, although it does bear on the relations that philosophy can or should establish with other theoretical and practical enterprises, including the sciences of man.

The sciences of man are the fifth issue in which naturalism makes a difference, and, indeed, it is the one that we shall now be concerned with. It inspires two distinct, though related, projects. The first is to 'naturalize' the mind: to show that the mind and all things mental are natural (Armstrong, 1968; Dennett, 1969; Fodor, 1975; Dretske, 1995). The second is to produce a naturalistic social science (Mill, 1843; Rosenberg, 2008).

On the negative, 'rebellious' side, naturalism takes the form, as was said earlier, of a rejection of the well-entrenched dichotomy between two kinds of science. This raises an immediate perplexity, akin to the one we encountered in relation to what constitutes genuine knowledge: naturalism rules out of bounds a large amount of research conducted in the sciences of man. If we assent to naturalism, for whatever reasons, we are left with the problem of disposing of the body of rejected research, both methods and results. Three main strategies can be deployed: wholesale elimination, wholesale reconstruction, or sorting and correction. Wholesale elimination is sometimes explicitly proposed: whether mainstream research is taken to be mistaken in its methodology – *verstehen* or interpretivism, hermeneutics, historicism, and so on – or in its basic assumptions – cultural relativism, social constructionism, omnipotence of the mind (its alleged capacity to develop any set of thoughts whatsoever), and so on – its output is consigned for the most part to the dustbin of history. But more often elimination proceeds tacitly: the results of mainstream research are essentially put to the side, and the ground is cleared for starting afresh, by picking the low-hanging fruit, accessible from the present stage of development of the natural sciences of sociality, and proceeding stepwise from there. Wholesale reconstruction rests on the thought that social scientists have unwittingly been going down the naturalist's path, while consciously following some official non-naturalist methodology. The aim is to redeploy all or most of the corpus of social science in a proper naturalistic framework, where it would blend seamlessly with results obtained directly from a naturalistic base. Finally, a naturalist social scientist may feel that throwing away the fruits of decades or centuries of work by mostly excellent minds is unreasonable, yet have no idea of how to reconstruct the entire field from first principles: she would then retain certain results that she has independent reasons to find at least approximately true or plausible, and attempt to correct and complete them with the help of natural science. This in fact is what is beginning to happen at the interface of the cognitive and social sciences (a good example is Elster, 2007).

Still, the main task of the naturalist, whether philosopher or social scientist, is to develop a naturalistic research program in the sciences of man, or, in other words, move from proclamation, conviction, or a priori arguments to existence proof: to show how and that a naturalistic account can be given of entities, processes, phenomena that have heretofore been regarded as out of reach of a naturalistic science. This is the stage where the naturalistic stance turns into a form of anchored naturalism, one that aims at making a scientific difference.

Naturalizing the Mind: Cognition, Brain, Evolution

The single most important reason why the discussion of scientific naturalism does not proceed today as it did in previous epochs is that biology has both matured into a full-fledged natural science and become hospitable to the human realm. Or so it was claimed earlier (Section Scientific Naturalism). It is important at this point to qualify this statement: without the rise of the formal sciences, biology would arguably not have developed into a bona fide natural science, and it would unquestionably not have become hospitable to the human realm.

The formal sciences are understood here to cover logic, in the broadest sense of the word, information and computer science, control and signal theory, theoretical linguistics and extend today to probability and statistics, dynamical systems, and mathematical modeling techniques in general. The unity and scope of this vast area is a topic beyond the reach of this article. The decisive point is the development of logic and information theory in the late 1930s, which led in short succession to the computer model of the mind, to generative linguistics, and to the information-theoretical approach in molecular biology and genetics. A few years earlier, statistics developed in such a way as to revolutionize and revive evolutionary theory. By the early 1960s cognitive science was born (though not yet baptized); initially understood as a computational theory of mental capacities, it rapidly expanded in several directions: first, it incorporated developmental psychology, so that the ontogenesis and the mature state of human capacities were seen as connected; second, the scope of cognitive science extended beyond the initial repertoire of learning, memory, reasoning, language, motor control, and absorbed emotions, consciousness, self, social skills; third, non-normal cognition and nonhuman cognition became integral parts of the study of cognition; fourth, partly as a consequence of the last point, neuroscience joined the federation, so that cognitive science crystallized in the mid-1970s into a multilevel, multidisciplinary integrative approach of the 'mind/brain.'

Two further additions were made to this structure beginning in the 1990s. First, the mutual dependence of the cognitive and social sciences became evident; second, evolutionary theory, which for many years was seen as no more than a lateral aspect of the problem situation, came to the fore, to the extent where an 'evolutionary social cognitive neuroscience' is seen by some as the inevitable result, in the coming years, of an ongoing process of multiple convergences. The present situation, though fluid, is more accurately described as a multipronged naturalization program of the human realm.

When the focus is on the individual, member of the *Homo sapiens* species, three avenues are open for investigation. First, the human individual has a complex of mental or cognitive capacities that can be characterized at the functional level of information processing; this is the mission of such fields as developmental psychology, psycholinguistics, experimental psychology; the computational models produced and tested may in principle have counterparts in artificial systems developed in artificial intelligence and robotics. Second, these capacities are undergirded by the brain: not only would there be no mind if there were no brain, but the complex structure of the mind depends on, and in fact faithfully reflects, the complex structure and workings of the brain, as the mind is seen as nothing over and above an integrated system of functions of the brain. An account of the latter amounts to a naturalization of the former. Third, these capacities are by and large functional in the biological sense, and are thus the outcome of biological evolution. Three distinct paths are thus thought to naturalize the mind, providing in the long run, respectively, (1) an abstract mechanical account of the information processing system; (2) a concrete biological account of the material system embodying the system; (3) an evolutionary account of the cognitive organ, described either at the functional, information-processing level (the evolved mind) or at the neural level (the evolved brain).

Are these programs bound to converge? The naturalist certainly thinks so. After all, the human body (and organisms in general) can be studied at the abstract functional level (models of the bodily functions can be constructed), at the anatomical, physiological, and metabolic level, and as a product of evolution by natural selection, and we do expect that these perspectives, as they are filled in, gradually blend into one unique, multidimensional picture. Indeed, this is the horizon in which many cognitive scientists frame their efforts. However there is a major difference: in the case of the human body, naturalization is not, or is no longer, an issue, and because we are antecedently assured of its natural status, these various investigations do not bear the burden of proving it, and by the same token we expect that they will converge in the long run. The case of the mind is different: each of the research programs is meant as a partial vindication of the claim that it is natural, and their convergence, if and when it is achieved, would likely be regarded as settling the issue, and also as showing how the respective ways in which the mind is 'naturalized' fit with one another. In the present stage of progress, no clear-cut conclusions are forthcoming: although our understanding has made impressive progress on many fronts, such that what may be called the 'natural profiles' of the mind are gradually coming into focus, the ultimate goal, namely proving beyond reasonable doubt that the mind is natural through and through in the operational sense of being fully accessible by natural science, remains elusive.

Indeed, how much of the mind is targeted by the naturalization program – what should be included in its final, completed 'natural profile' – is not entirely clear. Strict naturalism sees the mind as a natural system, and relies on natural science to account for both its invariant structure (allowing for development from birth to adulthood) and its particular processes. A (standard) physical system has invariant features and follows certain trajectories under various environmental

conditions, and both the features and the trajectories are under the jurisdiction of physics. Science however does stop short of singular happenings: a leaf falling from a particular tree at a particular time, thoroughly physical an event as it is, does not qualify for treatment by physics. Where to draw the line at which the mission of science ends is a vexed question even for physics (Cartwright, 1983). To a first approximation, the physics of a system stops where the contribution of the environment to the interaction overwhelms, in terms of complexity, that of the system: it includes types of trajectories under a variety of fairly simple environmental conditions, but not specific trajectories in highly complex situations.

When it comes to the mind, we would not expect science to account for the details of every episode of everyone's mental life, but only for the regularities that all such episodes exhibit, and for the shared functional architecture of the systems that produce them. A large part of the task is to define the basic concepts in terms of which to describe both. One proposal stemming from the formal sciences is to regard the mind as a set of information-processing functions operating on inner representations; in this framework, the aim of cognitive science is to characterize the types of mental states and the types of transformations on those states. Both states and processes raise a number of perplexities.

One essentially unsolved problem of particular importance is to provide a naturalistic account of the intentionality of mental states, that in virtue of which they represent (real or fictional) states of affairs – in brief, the challenge is to provide a naturalistic account of meaning (Millikan, 1984; Dretske, 1995). Another unresolved issue is that of consciousness, with many rival contenders vying with limited success for recognition as a naturalistic account (Block et al., 1996). A third conundrum is raised by the status of reasons in actions and behavior: reasons are prima facie distinct from causes, insofar as they obey incommensurable laws, yet enter in the commonsense explanations of action; naturalism demands that actions, and behavior generally, be explained in causal terms; so either, conceptual analysis notwithstanding, my reason for X-ing causes my X-ing, or it does not, despite the fact that absent my reason for X-ing, my X-ing is no longer an action but a mere movement (Davidson, 1980). Meaning and reasons both involve normativity: the mind seems to have a fundamental grasp of normativity, and to keep track of particular norms while orchestrating behavior that does or does not conform to the relevant norms. Making naturalistic sense of normativity appears to some philosophers as the most daunting task (Wedgewood, 2007; De Caro and Macarthur, 2010).

Important as they are to philosophers, these issues are less central for cognitive and social scientists, who are more anxious to find a principled way of drawing a boundary, within the dynamics of the mind, between what is due to the system and what to the environment. The nature/nurture debate, though transformed by what we have learned about development and plasticity, remains a bone of contention between naturalists and various strands of antinaturalists: if the mental dynamics owes a large part of its specific features to contingent or stable features of the history of interactions of the individual with her, mostly social, environment, then naturalizing the mind is an enterprise of limited scope, or so it seems (but see below). Nobody today doubts that there are natural constraints on what the mind can achieve, i.e., constraints on the mental dynamics; but the naturalists insists, and her opponents deny, that these constraints are of great import.

Most cognitive scientists involved in hands-on research, eager to avoid controversies which they see as fruitless, are in fact content with defending a modest naturalism, one which takes no stand on how far the naturalist account will eventually go, and what slack it will leave for the contingencies of the individual's life course, and/or the environmentally transmitted constraints originating in the social sphere. The real challenge lies in discovering the conceptual repertory in which to couch the natural constraints, not in attempting to second guess the extent of their reach.

Naturalizing the Social Sphere

Postulating, as has just been done, a clean separation between individual cognition and the social sphere is a gross oversimplification, and one that prejudges the issue of naturalism regarding the latter. And in fact naturalism is perhaps nowhere more salient as a challenger to established dichotomies than in the social sciences. Indeed, in some circles the mere fact that some phenomenon is under the influence of social factors implies *by stipulation* that it is not natural. This clearly assumes some particular character of *human* society, for what ants or bees do is regarded as no less natural for their being social species. Perhaps humans, also a social species, owe their natural character to both their individual and social constitutions. That is precisely what naturalism proposes; indeed, the most refined forms now under discussion aim to show that the naturalness of the human individual and the naturalness of human sociality are deeply intertwined.

Naturalism deploys three main strategies, either independently or in combination as the case may be, in its attempts to establish the natural character of the social sphere. The first is informational: society as a general phenomenon, as well as particular societies, are to a very large extent determined by the informational dynamics that they harbor. Information should be understood in a theoretical sense, shared with cognitive science, and in particular not limited to linguistic communication: many vehicles, including purely mental ones, carry and propagate meaningful tokens that in part determine both individuals' behaviors and the modification of the informational landscape. Game theory, which purports to provide a formal characterization of strategic interactions between agents, is a typical achievement of this strategy, one in fact which aspires to provide a unifying framework for the social sciences (Gintis, 2009).

The second strategy relies on cognitive science: by offering a detailed characterization of the individual mind, it narrows the set of possible social arrangements and facts. This need not presuppose a strong form of methodological individualism: a principle of individualistic transmission (Nelson, 1990), according to which any putative specifically social factor can have an impact only by impinging on individual members of the social group, is enough to make cognitive science relevant; in fact, it is irrelevant only on a strong form of social holism, claiming that the individual level of causality is screened out, and that the members of a group are indiscernible tokens that act as mere vehicles of social forces. Still, naturalism and

methodological individualism of one or another shade are regular bedfellows. Cognitive science, it is argued, substitutes genuine knowledge of human mental capacities, particularly memory, learning, reasoning, decision making, for intuitive notions or philosophers' speculations. As a result, behavior that is called irrational when it fails to conform to the latter yields to explanation in the light of the former. A new field, misleadingly labeled neuroeconomics, aims at providing an account of decision making based on cognitive neuroscience. Naturalism also harbors the hope to improve people's behaviors, in the sense of making them cohere better with their true preferences, for example by engineering the setting in which they make their choices so as to orient their natural decision processes in a more favorable direction (Thaler and Sunstein, 2009).

The third strategy rests on a general theory of evolution, with two distinct branches, biological and cultural. Biological evolution is called upon to account for the existence of cognitive mechanisms specifically geared to allow social interactions among humans to develop, stabilize, and evolve in particular ways, and which together constitute our shared 'social cognition.' Cultural evolution accounts for the genesis of particular forms of social processes, which generally (though not always) allow human groups to acquire new capabilities and capitalize on ones acquired at an earlier stage (Tomasello, 1999), at a considerably faster rate than biological evolution would permit. Two additional phenomena have recently enriched the explanatory toolkit of evolutionary approaches. The first is group selection, a highly controversial issue: the conjecture is that Darwinian selection can operate at the group level, so that one population may acquire as a whole a gene pool allowing it to outcompete another. Long widely regarded as discredited, the conjecture is alive again (Sober and Wilson, 1999). The second device is gene-culture co-evolution: a given gene pool favors the spread of certain cultural forms, that in turn favor individuals bearing certain genes, giving rise to a new gene pool (Richerson and Boyd, 2005). Niche construction, a phenomenon not limited to, but spectacularly exploited by humans, provides an illustration: the genetic endowment of a population leads it to alter its local environment in such a way that it become hospitable to variants which would otherwise be at a disadvantage. The variants thus flourish and go to fixation, leading to a genetically different population, well adapted to the niche that led to its selection (Odling-Smee et al., 2003). A niche need not be mainly material: those that matter most for humans are cultural.

Group selection and/or gene-culture co-evolution are harnessed for the resolution of several enigmas in standard biological evolution, bringing heretofore resistant phenomena within the purview of naturalism. The most important is cooperation, a central characteristic of humankind. Biological evolution in the Darwinian sense would seem to select exclusively self-regarding behaviors that destabilize in short order any cooperative system in which individuals contribute to the welfare of nonrelatives without expecting the favor to be returned. Another singular feature is the ability of human populations to adjust to an immense variety of habitats, which only a certain type of evolving culture can achieve; in turn, the selection process leading to inscribing in the human genome the ability to adapt to all sorts of environments rather than to a narrow range seems to require a co-evolutionary process. These examples are representative of a new orientation, within evolutionary psychology and anthropology, that anchors the study of culture in biology while granting it semiautonomous status (Richerson and Boyd, 2005; Sterelny, 2012; Wilson, 2002), rather than essentially reducing culture to a direct expression of our genetic endowment (Tooby and Cosmides, 1992; Pinker, 2002).

Naturalism inspires a large array of research programs in the social sciences, whose ambitions range from modest to revolutionary: they aspire to complement, reconstruct, or replace mainstream anti- or non-naturalistic approaches. A large part of the current efforts, and accompanying controversies, partake of methodological naturalism. A resolution of the age-old issue of *verstehen vs erklären* seems within reach, insofar as interpretation can be understood naturalistically: the meaning of human actions and events may in fact be objective properties, which social science can bring to light without renouncing the explanatory goal of natural science. A full reconciliation would seem to depend on several moves that are resisted by many (Taylor, 1971; Geertz, 1983) the discussion of which vastly exceeds the scope of this article. What does rather clearly stand out is the emergence of a significant body of naturalistic theory in the social sciences, which bypasses rather than confronts the interpretative tradition, by setting its own agenda and foregoing, in accordance with the lessons of biology, the demands of lawlike generality and predictability.

Fewer attempts are made to vindicate ontological naturalism. Still, the nature of social entities has come under sustained attention in the last quarter century. Social representations, institutions, norms, joint action, collective intentionality have been the focus of several proposals: Dawkins's theory of memes (Dawkins, 1976), Sperber's (1996) epidemiology of representations, Searle's (1995) theory of institutions as constitutive rules, the competing account of institutions as game-theoretic equilibria, pursued in the wake of Lewis's seminal *Conventions* (1969) by Skyrms (2010), Bicchieri (2006), and others, Gilbert's (1989) notions of plural subject and attached predicates such as collective belief, shared intention, etc., competing with accounts by Bratman (2014), Searle, Tuomela (2007), and others, Goldman's (1999) program for social epistemology, and so on. Here again, philosophical and formal theorists are under increasing pressure to share the field with empirical scientists, who bring data from developmental psychology, behavioral ecology, neuroscience, experimental economics, etc. that naturalism is committed to regard as relevant. Much remains to be done, however, before a clear picture of the viable options emerges.

Here as elsewhere, scientific naturalism in action, much like the sciences themselves, gradually refines its self-conception as it pursues the multiple theoretical, formal, and empirical inquiries inspired by its initial commitments: what 'nature' refers to, what are the admissible ways in which the entire repertory of entities attested in our practices, linguistic and otherwise, is in turn to be inscribed in nature, these are the terms of both the problem and the partial solutions proffered along the way. The process and its fallouts may well be more significant than any putative final vindication.

Nature and Society in Geography

Abstract

With a pedigree traced to antiquity, nature–society or human–environment inquiry vied for the identity of the modern discipline of geography as it emerged in nineteenth-century Germany. This identity involved the study of the human impact on and adjustment to the physical environment. For a brief period in the early twentieth century, a particular definition of the relationship, environmental determinism, dominated geographic education in the United States. The excesses and limitations of determinism relegated the nature–society identity in geography relative to a spatial–chorological one. This other and equally old identity remained largely unchallenged from the 1930s through the 1940s and onward. By the late 1970s, however, nature–society studies returned to geography in a significant way, building from interests that gave rise to cultural ecology and risk-hazard studies as well as several other subfields of study. Entering the twenty-first century, nature–society research in geography has grown in ways reflecting a range of perspectives found in the human sciences and humanities. Its future role in the discipline will be determined in part by the rise of new, interdisciplinary human–environment research communities, such as sustainability science.

Nature–society or human–environment relationships have been part of geographic inquiry since antiquity. The modern foundation of the themes of human impact on and adjustment to the physical environment, however, was articulated by nineteenth-century German geographers, with various claims that these relationships, broadly interpreted, constituted the identity of the discipline. For a brief period in the early twentieth century, a particular definition of the relationship, environmental determinism or the geographic factor, formally dominated geographic education in the United States. The excesses of determinism discredited nature–society studies in the discipline, with various attempts to embed human–environment relationships within the dominant spatial–chorological identity. By the late 1970s, however, nature–society or human–environment scholarship had returned to geography in a significant way, building from interests that helped to give rise to cultural ecology and risk-hazard studies as well as several other interdisciplinary subfields. Entering the twenty-first century, nature–society geography has grown significantly in the number of its practitioners and research influence, exploring the range of perspectives crossing from the sciences to the humanities. This rebirth coincides with renewed academic and public interests in the sustainability of the human–environment condition, whether such interests focused on climate change, ecosystem and biotic integrity, or sustainable development, and raises questions about the role of nature–society interests in the discipline of geography and in the academy at large.

Roots of the Theme in Geography

Ancient geography (Greek *geographia*, meaning writing about the Earth) involved descriptions of the Earth, serving to compile knowledge of places not experienced in everyday life and as found in travel and exploration. All places contain 'nature,' and most are occupied or used in some capacity by our species. It is not surprising, therefore, that 'complete' geographies documented the human and environmental character of places (Glacken, 1967). This substantive interest, in various intellectual forms, remains throughout the history of geography, although it continually struggles with other identities of the discipline in search of its intellectual niche.

German Foundations of Modern Geography

The nineteenth-century organization of knowledge within European academe shaped modern geography at a time in which the discipline was especially vibrant in Germany. The competing views expounded by German scholars during that century remain essential, if contested, elements of the discipline's identity in the twenty-first century.

The Spatial–Chorological Science

Immanuel Kant (1724–1803) laid the foundation for a spatial or chorological identity: geography provided integrative understanding through a focus on the spatial attributes and relations of phenomena as they were arranged in areas, regions, or space (Tatham, 1951: p. 40). This vision was elaborated in three ways by Karl Ritter (1779–1859), Ferdinand von Richthofen (1833–1905), and Alfred Hettner (1859–1941), among others. Geography was the science of areal or regional differentiation (and, hence, the need to bound or demarcate areas to inform understanding), the history and particularities of places (chorography), and distribution studies. These various identities, here collectively labeled chorology, generated a discipline based largely on a shared approach to, more than on a phenomenon of, study. This 'unique' quality, shared with history (Kant's chronological science), marked geography as an exception to the 'systematic' (science) disciplines, given its long-standing insistence that it is or large parts of it are a science.

The Nature–Society Science

Building on the natural histories of Comte de Buffon (1707–88), Johann R. Forster (1729–98), and Johann G.A. Forster (1754–95), an alternative identity of the discipline was championed by other nineteenth-century geographers, if not always explicitly. Alexander von Humboldt (1769–1859) set the stage for this vision of geography through such works as *Cosmos* (*Sketch of a Physical Description of the Universe*), which documented the 'unity in diversity' in nature, or how diverse phenomena, including humans, give rise to ordered, functioning landscapes (akin to the modern use of landscape in ecology). Humboldt was not especially interested in defining geography or articulating approaches within it, but he recognized three divisions of knowledge about nature, one of which he called geognosy (Earth science) and which dealt with the spatial distribution and relationships of phenomena (Dickinson, 1969: p. 24). This recognition along with his research approach, which involved bounding a landscape (thereby creating an areal unit), was consistent with chorology. Humboldt, however, had a phenomenon of study, the landscape, including the human alterations of it.

Unlike Humboldt, Frederich Ratzel (1844–1904) was keenly interested in the identity of geography and championed the view that the discipline should be a systematic science, complete with a phenomenon of study, the nature–society relationship (Dickinson, 1969: p. 65, Tatham, 1951: p. 64). In *Anthropogeography: Introduction to the Application of Geography to History* (1882), Ratzel advanced a science of reciprocal relationships between nature and society in which the distribution of cultures (his students employed 'cultural area' before the term emerged in anthropology) was predicated on a Darwinian-influenced notion of the capacity of different societies to adapt to their physical surroundings, also referred to as landscape. Ratzel focused on human adjustments to and manipulation of natural resources and environmental conditions, although subsequently others would reverse this orientation.

Other German geographers of the time followed partially, if not fully, the Ratzelian view. Otto Schlüter (1872–1952) found fault with the environmental orientation in the emerging nature–society thought (Dickinson, 1969: p. 126), but he saw the scope of geography as understanding the 'visible' landscape (*landscahft*), not as a bounded area but as the nature–society relationships shaping it (Livingstone, 1993: p. 264). Albrecht Penck (1858–1945), among others, found merit in this view, favoring a landscape-led geography akin to Schlüter's view (Dickinson, 1969: p. 110). From this point onward, landscape would hold different meanings to different geographers. Regardless of the specific definition used, the landscape concept invariably implied a collection of organic and inorganic phenomena (or an aggregate phenomenon) whose interrelationships gave rise to some meaningful areal identity on the Earth's surface, be it a coastline, system of cultivation, or urban settlement.

Ties between the Two Views

Chorology and nature society were linked historically. Human–environment proponents did so by focusing on landscapes bounded as areal units. For example, Vidal de la Blache (1845–1918) and, to a lesser extent, his student, Jeans Brunhes (1869–1930), both influenced by Ratzel, organized French geography around nature–society relationships as they were manifested in small areas and recorded in regional monographs. German chorologists, in contrast, invariably called for the examination of the place, area, or region, which axiomatically included human–environment relationships. Ritter's own work, *Erdkunde*, is exemplary, as registered in the subtitle (*Earth Science: in Relation to Nature and the History of Man*) and in the text: "The earth and its inhabitants stand in the closest reciprocal relations, and one cannot be truly presented in all its relationships without the other" (in Tatham, 1951: p. 44).

The Geographic Influence or Geographic Factor

The nature–society position vied for the sole identity of the discipline as it emerged in the United States during the early part of the twentieth century. There, geography's birth was influenced by William Morris Davis (1850–1934), a geomorphologist of no small repute, who created a geography program within geology at Harvard and was the force behind the creation of the Association of American Geographers (1904), serving as its president three times. He increasingly came to view geography as the study of inorganic (nature) controls over the organic (society). In his 1905 Presidential Address to the Association of American Geographers, he not only made the case for the study of this relationship as the defining element of geography, but also disposed of the chorological position in two brief sentences.

> There is so little support for this narrow view of the subject [location] to be found in modern geographical books that it need not be further considered [and] … if geography were only the science of distribution, that is, the regional aspect of other subjects, it would be hardly worth while to maintain the study of geography apart from that of the subject whose regional aspect it considers. (in Johnson, 1954: p. 9)

The strength of Germanic influences on Davis is unclear. He referenced and critiqued German geographers, but his views of geography may have been more strongly affected by the Darwinian and neo-Lamarckian fervor of the time and the search for organic analogy (Livingstone, 1993: pp. 203–205). His position was shared, even anticipated, by a number of highly productive geographers who were well versed with the German traditions, none more important than Ellen Churchill Semple (1863–1932) of Clark University and the University of Chicago. Mentored by Ratzel, she championed the theme of *geographic influence* or the *geographic factor* as articulated in *Influences of Geographic Environment* (1911). She was joined in this vision in the United States by such luminaries as Ellsworth Huntington (1876–1947) at Yale, a prolific author who sought to understand the history of regions through the lens of climate (e.g., *Civilization and Climate*, 1915), and abroad by Griffith Taylor (1880–1963), among others, who attempted to explicate the controlling constraints of environment on human occupation of different

lands (e.g., *Australia, A Study of Warm Environments and Their Effect on British Settlement*, 1941).

Taken as a whole, this group of geographers paid little, if any, attention to alternative or linked views of the identity of the discipline. Enhanced by the elite private institutions in which Davis, Huntington, and Semple were positioned, their moment of power penetrated the very foundations of American education. The Conference on Geography in 1892 adopted the Davisian identity of geography, which in turn was accepted by the Committee of 10 of the National Educational Association (1892), whose role it was to define precollege educational programs and college entrance requirements (James and Martin, 1981: p. 290). The discipline was thus defined as the study of inorganic controls over the organic, or the geographic influence factor, and its K–12 textbooks were organized accordingly.

The ascendancy of this human–environment identity was short lived. The geographic factor narrowed the human–environment relationship to the search for the causal power of nature over society – an extreme form of human adjustment or paucity thereof to nature. Alternative views of the relationship, such as the possibilism of the French geographers or by the American, George Perkins Marsh (*Man and Nature or, Physical Geography as Modified by Human Action*, 1864) on the environmental impacts of human activity were unheeded. The geographic factor became *environmental determinism*, which, in its lay applications, not only led to unfounded simplifications about nature's influence on humankind but also were drawn on as support for social and political views proposing the superiority of northern environments and peoples over all others.

The extremes of determinism devastated geography and seriously wounded the nature–society position. The stigma attached to the geographic factor was so strong that by the 1940s human–environment interests were relegated to the margins of the discipline and were even dismissed by some historians of the field (Livingstone, 1992: p. 6). For much of the middle of the twentieth century, the central intellectual debate in US geography centered on the kind of spatial–chorological science geography should be: a place-based and areal differentiation science (Hartshorne, 1961), or a science of spatial relationships (National Research Council [U.S.] 1965). The former focus was open to human–environment relationships (above 2.3), whereas the latter focus was indifferent to them. By the 1960s, the latter focus gained intellectual hegemony among the leadership of UK and US geography, remaining in power for two decades before it succumbed to challenges that reinserted the role of the contingencies of place and regions (*see* Geography: Overview). These challenges notwithstanding, geography's identity remains linked primarily to the 'why of where' question, and much of human geography dismisses nature–society studies or sees them as falling outside the 'human' domain of the discipline's study (*see* Geography: Overview).

Alternatives to the Geographic Influence

If the 'battle' for the identity of geography were lost by proponents of the geographic influence, strong geographic interest in nature–society themes persisted. At least two alternatives to environmental determinism arose before its collapse, each providing the foundation for contemporary nature–society studies in geography. Carl O. Sauer (1889–1975) sketched his alternative vision in his 1925 essay, 'The Morphology of the Landscape.' Inspired by German scholarship, Sauer sought to bring the discipline back to the landscape (an area of interrelated phenomenon), whose qualities as a whole (form, structure, and function) constituted a reality not captured by the constituent parts separately (in Leighly, 1963: p. 321). The landscape was a nature–society relationship, and the morphology was a method of synthesis, a "massing and ordering phenomena as forms … integrated into structures" (1963: p. 326). He argued that there was "a strictly geographic way" of entertaining these structures, and it was through the material imprints that society made upon area (1963: p. 326). Thus, Sauer's nature–society relationship was the human impact on the 'physical whole' (i.e., nature and the built environment) which created the landscape.

Whatever Sauer's views on the ties between nature–society and spatial–chorological geography, he and the research prodigy of the 'Berkeley school' produced a large number of works focused on the human use of and impact on the Earth, including Sauer's own role in *Man's Role in Changing the Face of the Earth* (Thomas, 1956). Exemplary was Philip Wagner's *The Human Use of Earth: An Examination of the Interactions Between Man and His Physical Environment* (1960), which provides only passing references to alternative identities of geography before exploring a discipline devoted to the human-made landscape. Such nature–society interests were taken up outside the United States under the rubric of cultural or historical geography (e.g., Darby, 1940; Williams, 1974).

Harlan Barrows (1877–1960) laid the foundation for the other nature–society theme in his 1922 Presidential Address to Association of American Geographers. He proposed geography as the study of human ecology or the adjustment that humankind makes to the occupied environment (Barrows, 1923). Here was an explicit statement that nature–society relationships were the foundation of the discipline, and that this foundation need not be deterministic. Barrows' call had no immediate discernible impacts, but some 30 years later his former student, Gilbert F. White (1911–2006), returned to Chicago to pioneer risk-hazards geography. White was captured by the service role that academic research could provide for solving social problems and was not particularly responsive to academic debates about the discipline's definition. Nevertheless, the defining quality of his interests and the geographic work he advanced was a form of human–environment relationship, specifically human adjustments to environmental perturbations, articulated in Ian Burton, Robert W. Kates, and Gilbert F. White, *The Environment as Hazard* (1978) (*see* Gilbert F. White).

Thus, geography entered the 1960s with two strong research communities addressing nature–society themes: human use and impact on nature, and human responses and adjustment to environmental change and perturbations. Arguably, a large number, perhaps even a majority, of these practitioners were drawn to geography primarily out of its human–environment traditions and the paucity of them in most other disciplines (Kates, 1987). For the most part, however, the nature–society

practitioners were content to do their work and made minimal attempts to challenge the identity of geography as a chorological science.

Contemporary Nature–Society Subfields in Geography

By the 1970s, nature–society research in geography was prospering, but under newly emerging or expanding subfields to which geographic organizations were partitioning themselves. These subfields initially were stimulated by systems and ecosystems approaches combined with theory-driven, behavioral analysis (Harden, 2012; Turner and Robbins, 2008; Zimmerer, 2010). The *environmental hazard* subfield was in full swing, having taken on virtually every type of environmental perturbation to human occupation and use of the environment, from drought to volcanic eruptions. Research began to expand into non-Western world contexts, and a search for generic templates of human responses to such perturbations was under way. Hazards research spawned risk assessment and technological hazards and, more recently, informed by critique of it, vulnerability assessments (e.g., *see* Environmental Risk and Hazards; Environmental Vulnerability). A complementary subfield, *environmental perception and behavioral geography*, moved toward issues of the bounding the human–environment experience and its meaning for hazard adjustments and landed resource use more generally.

The *cultural ecology* subfield in geography arose from the cross-fertilization of practitioners whose legacy may be seen in the substantive interests in the landscape but with the goals and aims articulated by Harold C. Brookfield in Australia on household and community behavior and Karl W. Butzer in the United States (via Canada and Germany) on systems (e.g., *see* Ecology, Cultural Geography). Increasingly, the work of cultural ecologists in geography and anthropology blurred as attested in work by, for example, Robert McC. Netting (1934–95), Emilio Moran, and William M. Denevan.

By the 1980s, both environmental hazard and cultural ecology were strongly affected by Marxist and critical approaches, and in the 1990s by social theory broadly conceived, with various impacts on the two subfields (Turner and Robbins, 2008). *Political ecology* emerged (Blaikie and Brookfield, 1987), directing attention to local nature–society conditions as a product of social differentiation (e.g., power, wealth, class, gender) and of linkages to distant decisions and processes. Many proponents were interested in both the drivers of and responses to environmental change and linking the two, dissolving some of the distinction that existed between cultural ecology and risk-hazard research. In addition, political ecology research in its various renditions broke down the partitions in nature–society research between 'pure' and 'applied' work, as did its risk-hazard counterpart, (e.g., *see* Feminist Political Ecology; Ecology, Political).

Contemporary agriculture and rural land use and *water resource* subfields emerged to tackle current nature–society problems, primarily in the developed world (e.g., *see* Water Resources). Both experienced similar intellectual influences that gave rise to political ecology. The *human dimensions of global environmental change* emerged in the 1990s as a hybrid of the other subfields – one that appealed to global environmental change and sustainability themes (Turner et al., 1990). More recently, subfields such as land change science have emerged (Turner et al., 2007).

Mirroring the cacophony of perspectives in play in the natural and human sciences and humanities, nature–society practitioners have explored a wide range of frameworks for understanding (Turner and Robbins, 2008): postpositivistic science, to critical and social theory, to the search for meaning in the symbolic landscape (e.g., see Cultural Landscape in Environmental Studies). An appreciation for such diversity and the ability to move among the various frameworks have long been hallmarks of geographic work. After a period in which different communities sought to advance competing frameworks or perspectives for understanding human–environment systems, much nature–society geography has now refocused, informing concepts and problems in the way that its intellectual ancestors might have imagined, if not the kinds of questions and issues addressed. That work is strongly empirical and increasingly quantitative, but it is responsive to qualitative data and methods and focused on the material relationships between humankind and the physical environment, whether it is human-induced land degradation or equity in opportunities to respond to it. Explanatory models seek to treat more equitably than before actor-based and structural-based approaches and to consider the roles of context, idiosyncratic agents, and historicity (path dependence). Additionally, the environment as an active force within the relationship has been reinstated, albeit examined through such themes as nonstationarity, complexity, system thresholds, and coadaptation. The former barriers between human use–impact and human response–adjustment studies have all but disappeared. In addition, nature–society practitioners may be poised to tear down the blinders of established explanatory perspectives, seizing the moment of 'hybrid explanatory vigor' to formulate improved understanding of the human–environment relationship (Turner and Robbins, 2008).

Geography as Nature–Society Science?

Do these trends suggest that geography is poised to redirect its identity to nature–society relationships? Probably not, although Stoddart (1987) came very close to making such an appeal, and Peet (1998) argues for a variant of such a move. To adopt this identity, retain the spatial–chorological one, or, better, to unite the two, requires resolution of several intellectual and pragmatic considerations confronting a restructuring academy.

What Other Disciplines Concede

May (1970: p. 186) argued that no other discipline claims the nature–society relationship and most concede the subject to geography. As well, three of five texts granted the status as paradigmatic shifts in geographic practice by Harvey and Holly (1981) belong to Ratzel, Vidal de la Blache, and Sauer, all of which can be interpreted as nature–society visions as much as, if not more so, than spatial–chorological visions. May's observations, however, ran counter to those by Hartshorne

(1961: pp. 124–125), who argued that the other human sciences 'must' address nature–society relationships "to understand the different social conditions of different lands and places." Save for anthropology and resource and environmental economics, however, the human sciences have largely ignored these relationships (e.g., Goldman and Schurman, 2000), at least until the recent rise of public and government concerns about them. If Hartshorne erred, was May correct? Human–environment geographers have played a major role in the creation of interdisciplinary research institutes and international organizations and programs dedicated to climate and global change and sustainability; their impact in these endeavors has been far out of proportion to their numbers in the academy at large. The very interdisciplinary qualities of these activities, however, raises questions about how much the 'core' of nature–society studies is embedded in any one discipline.

Unified Understanding

Does a nature–society identity provide unity to geographic understanding? Again, Hartshorne was adamant that it did not, drawing on Hettner's argument that the "logical unitary structure of geography [is] … destroyed" by the dualism inherent in the nature–society position, whereas "if the concept of nature and man proceeds from the chorological viewpoint, it is homogeneous in all important points" (in Hartshorne, 1961: p. 123).

Hartshorne provided little support for Hettner's claim, as if the weight of history were sufficient to prove the point. But this history is not necessarily borne out in contemporary geography in which the divisions between human and physical geography have grown, and frameworks for unification drawn from the spatial–chorological position do not necessarily speak to nature–society interests (but see Hanson, 1999). Contemporary attempts to articulate the unity of geography through the nature–society position are few. In principle, however, there is no reason why a focus on the relationship should create the dualism noted, and various reasons why it should lead to more integrative or unified views of humankind and the physical world. Indeed, this last rationale is precisely that used to justify the investment in the many interdisciplinary sustainability programs, centers, and institutes emerging worldwide.

Nature–Society and Geography as Practiced

What passes for accepted practice in large measure shapes the identity of disciplines. Pattison (1964) identified four traditions or domains of research practiced in geography in the mid-1990s, which are still appropriate in the twenty-first century, allowing for name changes: mapping sciences, physical or environmental geography, space–society studies, and human–environment studies. Privileging the nature–society domain as the identity of geography encounters problems rationalizing the existence of the other three domains as independent subjects of study. Barrows and other proponents of the nature–society position of yesteryear noted this predicament and dealt with it by dismissing the other domains, save as they were needed to understand nature–society relationships. Peet (1998: pp. 1–3) linked nature–society and spatial–chorological geography by insisting that nature–society relationships could be understood only in real-world relational space. In this interpretation, space is the 'veneer' of nature–society relationships, such that to examine spatial relationships axiomatically involves nature–society relationships. Alternatively, Sack (1997) explored a way in which nature and society can be reconciled without the reductionism employed by the natural and some social science approaches. This treatment is accomplished by focusing on places because, according to Sack, place (a bounded area) is the instrument that humankind uses to combine nature and society, or the forces and process of each. Without place, understanding privileges nature, society, or a particular explanatory form drawn from one or the other. With place, however, a 'less privileged' understanding is possible. Should this understanding be forthcoming, perhaps the long-standing tensions between the two visions of geography might dissipate. It is noteworthy that these attempts to link the two identities mimic those that have been made in past, but with different language.

Nature–Society Geography Entering the Twenty-First Century

What is and ought to be humankind's relationship with nature? This question remains one of the most fundamental and vexing confronting our species (Kates, 2001). Geography has long claimed much of this question as its own, and perhaps has devoted more attention to its various elements than any other formal discipline of study. This tradition, strongly muted during the mid-twentieth century, perhaps reflecting geography's self-image vis-à-vis environmental determinism, revived significantly by the 1990s in concert with the rise internationally of multidisciplinary research foci variously labeled global environmental change and sustainability, and the emergence of new perspectives and methods for nature–society studies. Rebuilding on its past, human–environment geography may offer the largest number and array of researchers from any discipline experienced in bridging the natural and human science components of these concerns.

Reinvigorated in this way, the contributions of the nature–society domain of geography appear to stand on equal footing with those of all other geographic domains of study (National Research Council, 1997, 2010).

This circumstance, however, has come at a moment when the academy at large has discovered integrated human–environment studies, referred to in the literature as social–ecological systems, human and natural systems, and human–environment system – all forms of complex adaptive systems. International programs of research, such as the Global Land Project, DIVERSITAS, the Program on Ecosystem Change and Society, and the Resilience Alliance, are under way to advance human–environment research, while the International Council of Science reconfigures the global change research program accordingly under the rubric of Future Earth. In tandem, institutions of higher learning internationally are creating degree programs to foster this integrated understanding and which tend to maintain the label 'sustainability' in their titles. A series of new journals

(e.g., *International Journal of Sustainability*, *Sustainability: The Journal of Record*) and sections of established ones (e.g., *Proceedings of the National Academy of Sciences, USA*) serve the science and scholarship emanating from sustainability science and related studies. All of these and other efforts may be creating a new, integrated human–environment science independent of established disciplines, such as sustainability science, which take the human–environment system as its phenomenon of study. The outcome of these dynamics will determine the role of nature–society geography within and without the discipline.

Nature-Nurture Controversy, History of

Christopher R Badcock, London School of Economics, London, UK

Abstract

The nature/nurture distinction originated with Francis Galton, who was also the first to realize that twin studies could provide a crucial test of the contributions of each. Both behaviorists and social scientists made extreme claims for nurture during the twentieth century. In the Soviet Union Lysenkoism enshrined nurture over nature as a dogma of Marxist biology while in the West scientists who failed to subscribe to a less dogmatic equivalent were subject to campaigns of casuistic criticism and character assassination. Findings from experiments of nature such as feral children and attempted gender-assignment contrary to chromosomal sex, along with recent evidence from autism, Turner's syndrome, and the link between monoamine oxidase A and antisocial behavior suggest that Galton was substantially correct in thinking nature to be the dominant factor. But the recent discovery of epigenetic factors, which for example explain genetic differences between identical twins, suggests caution in accepting the traditional terms of the debate at face value.

Origins of Nature/Nurture: Francis Galton

Sir Francis Galton (1822–1911) introduced *nature* and *nurture* as understood with their modern connotations in his book of 1874, *English Men of Science: Their Nature and Nurture*. According to Galton,

> The phrase "nature and nurture"… separates under two distinct heads the innumerable elements of which personality is composed. Nature is all that a man brings with himself into the world; nurture is every influence from without that affects him after birth.

Galton was careful to add that "Neither of the terms implies any theory: natural gifts may or may not be hereditary; nurture does not especially consist of food, clothing, education or tradition, but it includes all these and similar influences whether known or unknown" (Galton, 1874: p. 12).

He went on: "It is needless to insist that neither is self-sufficient; the highest natural endowments may be starved by defective nurture, while carefulness of nurture can overcome the evil tendencies of an intrinsically bad physique, weak brain, or brutal disposition" (Galton, 1874: pp. 12–13). Galton concludes that "In the competition between nature and nurture, when the differences in either case do not exceed those which distinguish individuals of the same race living in the same country under no very exceptional conditions, nature certainly proves the stronger of the two" (Galton, 1874: p. 16).

Galton noticed that "There are twins of the same sex so alike in body and mind that not even their own mothers can distinguish them" (Galton, 1874: p. 13), and made a distinction between what we would now call identical, or monozygotic (MZ) twins (those which developed from a single fertilized egg cell) and fraternal, or dizygotic (DZ) twins (which develop from different eggs). Although Galton remarked that "It occurred to me that the after-history of those twins who had been closely alike as children, and were afterward parted… would supply much of what was wanted…" (Galton, 1869: pp. 294–295) he did not propose that the resemblance of MZ twins be compared to the resemblance of DZ pairs to assess genetic influence. Only much later in 1924, did Curtis Merriman in the USA and Hermann Siemens in Germany realize that MZ twins separated at birth provided what appeared to be an acid test of nature versus nurture because it was presumed that their common genetics held nature constant while their different environments varied the factor of nurture (Rende et al., 1990).

Making a Case for Nurture: Behaviorism

Galton was candid enough to admit "that my evidence may seem to prove too much, and be discredited on that account, as it appears contrary to all experience that nurture should go for so little" (Galton, 1874: p. 16).

The behaviorist John Broadus Watson (1878–1958) famously claimed that: "we no longer believe in inherited capacities, talent, temperament, mental constitution, and characteristics. Give me a dozen healthy infants, well-formed, and my own specified world to bring them up in and I'll guarantee to take any one at random and train him to become any type of specialist I might select – doctor, lawyer, merchant-chief and yes, even beggar-man and thief, regardless of the talents, penchants, tendencies, abilities, vocations and race of his ancestors." He admitted that "I am going beyond my facts and I admit it," but added, "so have the advocates of the contrary and they have been doing it for many thousands of years" (Watson, 1930: p. 82).

Experiments by John Garcia showed that rats could be conditioned to associate the size of a food item with an electric shock, but that rats cannot be conditioned to associate a shock with the taste of food. Again, when paired with X-rays causing illness 1 h later, rats learn to associate the taste of food with illness, but cannot learn to associate the size of food items with illness caused in the same way. Clearly, insects with stings and poisoned baits that rats naturally encounter in their habitat might account for why the animals associate size with shocks, and taste with poisoning. But taste would seldom if ever be naturally associated with an instantaneous insult, and the size of a food item is no clue to its toxicity. In a similar way, pigeons

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03136-6

cannot be conditioned to associate odor or sound with food, but will readily associate its appearance. And even though pigeons quickly learn to peck an illuminated key before food is delivered because pecking is a natural food-finding activity, attempts to condition them not to peck the key by making pecking it prevent the food reward have no effect. On the contrary, once established, pecking persists, even if the pigeon starves to death as a result (Garcia, 1981, 1990).

In short, there are definite limits to conditioning, even in the case of classic laboratory animals such as rats and pigeons, and it would be astonishing if the same were not even more true of human beings.

The Cultural Claims for Nurture

Parallel claims to those of behaviorists for the overriding importance of nurture over nature were made by numerous social science writers, notably Franz Boas (1858–1942) and his colleague, Alfred Louis Kroeber (1876–1960). But these claims remained mere assertions until Boas's student, Margaret Mead (1910–78) wrote *Coming of Age in Samoa*, which purported to provide ethnographic proof that nurture was indeed the dominant factor – at least in Samoa (Mead, 1928).

However, the anthropologist, Derek Freeman, followed in her footsteps in the 1960s, and published a series of books suggesting otherwise. For example, Mead claimed Samoans were "one of the most amiable, least contentious, and most peaceful peoples in the world" but Freeman reports that serious assault in mid-1960s Western Samoa was 67% higher than in the USA, 494% higher than in Australia, and 847% higher than in New Zealand, while common assault was 500% that of the USA. In Samoa according to Mead "love between the sexes is a light and pleasant dance," male sexuality "is never defined as aggressiveness that must be curbed," adding that "the idea of forceful rape… is completely foreign to the Samoan mind." But Freeman reports that rape convictions in Samoa of the 1960s were twice the level of those in the USA and 20 times those of the UK. At the time Mead was in Samoa, rape was the third-most common criminal offense. Whereas Mead claimed that young girls had "as many years of casual love-making as possible" before marriage, there was in fact a cult of virginity; and contrary to her portrayal of it, the pattern of adolescent crime was much the same as anywhere else. Eventually, Freeman obtained a confession from one of Mead's informants and concluded that Margaret Mead's credulity for nurture over nature had led to her being hoaxed by her Samoan informants (Freeman, 1983, 1998, 2000).

According to Judith Rich Harris, the usual view of cultural transmission – that the culture is passed down from the parents to the child – is inadequate and misleading. An example is language in the USA. The children of immigrants who speak English with a heavy accent end up speaking English with no foreign accent at all if they grow up in a neighborhood of native-born Americans. Harris thinks that other aspects of culture are transmitted in the same way as language. In developed societies the parents start the process at home, but whether children retain what they learned at home will depend on what they find outside. Indeed, she claims that there are many societies where the parents hardly talk to their babies at all, and the babies do not learn language until they graduate from their mother's arms into the local playgroup. They learn both the language and how to behave from the older children in such groups, making peers the most important factor in nurture (Harris, 1999).

Politics Against Nature: Lysenkoism in the USSR and Parallels in the West

Mead's close contemporary, Trofim Denisovitch Lysenko (1898–1976) was promoted through positive discrimination in favor of peasants by Marxist revolutionaries in the USSR, and ultimately became Stalin's biology czar. Lysenko took the nurture-not-nature ideology of official Marxism to bizarre and extreme lengths, claiming that crops could be 'educated' to grow in winter (so-called *vernalization*), and that such learning was heritable. Lysenko denounced Mendelian genetics as a 'capitalist' and 'clerical conspiracy,' and denied the existence of genes, hormones, and viruses. Lysenko also unconditionally accepted the inheritance of acquired characteristics, denounced natural selection as 'Darwin's greatest mistake,' claimed species could transform into one another without intermediate steps, and believed that fish in puddles arose from spontaneous generation (Medvedev, 1969)!

Astonishingly, Lysenkoism became the official genetic doctrine of the USSR until the mid-1970s, and after 1948, thousands of scientists were purged, tortured and murdered in detention, or died of starvation and exposure exiled in Siberia. The teaching of Mendelian genetics and criticism of Lysenko's environmentalist inheritance became a crime, and Soviet agriculture was forced to adopt Lysenko's methods, with disastrous consequences that contributed to widespread famines and food shortages (Gershenson, 1990; Medvedev, 1969).

But such proscription of genetics was not limited to the USSR: in a less official form it also affected the USA, as the extract from the following letter, signed by 50 scientists and published in *American Psychologist* in July 1972, eloquently attests. After citing "periods when scientific research or teaching was censured, punished, or suppressed for nonscientific reasons, usually for seeming to contradict some religious or political belief," and naming Galileo, Darwin, Einstein, and 'Mendelian biologists, in Stalin's Russia,' as cases, the letter continues to point out that

> Today, a similar suppression, censure, punishment, and defamation are being applied against scientists who emphasize the role of heredity in human behavior. Published positions are often misquoted and misrepresented; emotional appeals replace scientific reasoning; arguments are directed against the man rather than against the evidence… And a large number of scientists, who have studied the evidence and are persuaded of the great role played by heredity in human behavior, are silent… it is virtually heresy to express a hereditarian view, or to recommend further study of the biological bases of behavior. A kind of orthodox environmentalism dominates the liberal academy, and strongly inhibits teachers, researchers and scholars from turning to biological explanation or efforts.
>
> Page (1972)

Examples of the abuses mentioned in this quotation are character assassinations of leading researchers who continued the start made by Galton on testing intelligence and its links to heredity or to physical factors such as brain-size or race. In a press campaign reminiscent of those whipped up by Lysenko, the leading British researcher, Sir Cyril Burt (1883–1971) was accused of wholesale scientific fraud after a biographer had revealed some of complexities of Burt's character and sometimes unconventional working methods (Hearnshaw, 1979). But in 1989 and 1991, the psychologist Robert Joynson (Joynson, 1989) and the sociologist Ronald Fletcher (Fletcher, 1991) independently showed that the attack on Burt had no factual basis. On the contrary, Burt's claim that identical twins reared apart have IQs correlated at 0.77 has been vindicated by the Minnesota Twin Study, which found 0.78 (Rushton, 1994).

According to Stephen J. Gould in his influential book *The Mismeasure of Man*, Henry H. Goddard's (1866–1957) pioneering work on IQ in the USA was aimed at "preventing the immigration and propagation of morons." But Goddard's own conclusion was the opposite: he believed that immigrants' low IQ scores would rise in better social conditions in the USA and asserted that "we may be confident that their children will be of average intelligence and if rightly brought up will be good citizens…" Again, contrary to Gould's portrayal of the facts, Lewis Terman (1877–1956) reported high IQs of Jewish and oriental immigrants, and IQ testers such as Goddard and Terman did not advocate restrictions on US immigration like those of the 1924 act. In fact, Congress took little or no notice of IQ findings in framing the legislation, none of the major testers testified, and their publications were not cited in the legislative record. And although Gould claimed that Samuel G. Morton (1799–1851) "unconsciously" doctored cranial capacity measurements to endorse Caucasian "racial superiority," remeasurement by John S. Michael in 1988 found few errors – and those not in the direction asserted by Gould. Michael concluded that Morton's research "was conducted with integrity" and that Gould was "mistaken" (Rushton, 1997).

Test Cases: Sex Determination

The reports of Mead and others were often interpreted as evidence for nurture against nature, and another example might be the claims of John Money (1921–2006), a psychologist at Johns Hopkins University, who held that sex was socially determined in childhood and could be reassigned up to age three. He based these claims principally on the case of 'Brenda' Reimer, one of a normal pair of twin males who was castrated following a botched circumcision and reassigned female by Money in the 1960s – the first ever attempt to do so with an otherwise normal male. Indeed, the case became paradigmatic as an apparent proof of the power of nurture over nature until later revelations revealed an altogether different story of a conflicted child who refused to wear dresses from the start, rejected girls' toys, was described as "boyish" by teachers and who changed his official name to Bruce. Bruce Reimer revealed the coercive side of the nurture dogma when he described himself as a David versus the Goliath of the medical profession and society and eventually married, adopted children and worked in an all-male occupation until he committed suicide in 2004 following the break up of his marriage and suicide of his twin 2 years earlier (Colapinto, 2001).

In the medical literature as a whole "there is no known case where a 46 chromosome, XY male, unequivocally so at birth, has ever easily and fully accepted an imposed life as an androphilic female regardless of physical and medical intervention" (Diamond and Sigmundson, 2000). On the contrary, a study of 18 cases of pseudohermaphroditism due to 5-α-reductase deficit in the Dominican Republic raised as girls who underwent normal male puberty found that 15 made a full sex-role change and were living with women at the time of the study (Imperato-McGinley et al., 1979). Similar findings were reported regarding the same pseudohermaphroditic syndrome among the Simbari Anga of Papua New Guinea who had a radically different culture from that of the Dominican Republic: after male initiation rites prior to puberty the two sexes are kept rigorously separate, and ritualized oral sex occurs between men from puberty until premarital age (Imperato-McGinley et al., 1991; LeVay, 1993: p. 134).

Experiments of Nature: Feral Children

A natural nature/nurture experiment is presented by feral children who provide potential answers to the question of how a child would develop if not nurtured at all, or nurtured by animals, and a surprisingly large number of cases are known. A classic example is The Wild Boy of Aveyron, who was discovered aged 12, living in woods in the late 1700s and found to be mute – but not deaf. He was taught some sign language by a local doctor who was a follower of Rousseau and a believer in the power of nurture over nature, but never spoke or developed social skills or attachments despite the best efforts of his mentor (Losure, 2013).

A modern equivalent is provided by the case of Genie, who was kept chained to a stool in a darkened room in a suburb of Los Angeles for years. Thought to be six on discovery, she was found to be a 49 lb, 3′8″ teenager who was permanently bent over, unable to walk, incontinent, and unable to focus on distant objects. Genie was fostered with psychologists who were enthusiastic about her prospects of rehabilitation, but she never acquired any real language ability, despite their best efforts (Rymer, 1993). However, better results were obtained with Justin, a boy who was raised as a dog. Justin was left with his grandmother aged 2 months until she died 11 months later, and was then raised by her boyfriend along with his dogs in a kennel. Discovered at age five unable to walk or talk, he was fostered and made a remarkably rapid recovery, doing well at school and speaking normally (Perry and Szalavitz, 2006).

Of course, all such cases are anecdotal, but a larger sample was provided by 165 Romanian orphans who were brought to the UK in the 1980s. Most were under a year and had suffered extreme neglect in state orphanages, but by age four, most had recovered. Eleven older children showed signs of autism, but by age six most symptoms had ameliorated and their IQs increased by 20 points compared to an average increase of 7 points in the rest of the group (Frith, 2003: pp. 50–51).

The Lesson of Autism and Turner's Syndrome

Autism is another test case, since this early onset illness evidenced by deficits in social and mentalistic skills (often with severe withdrawal, language delay or complete mutism) was claimed to be caused by nurturing – or the lack of it – by "refrigerator mothers" (Bettelheim, 1967).

Today, however, autism is widely accepted to be a genetic – or at least epigenetic – disorder, and demonstrably runs in families, with high concordance in identical twins (Aitken, 2008). Nevertheless, and despite the fact that all autistic children show some kind of learning difficulties and that many are severely retarded, so-called *autistic savants* demonstrate remarkable abilities, invariably in mechanistic, computer-like skills, most notably and frequently calendar calculation, maths, and music (Treffert, 2000). To the extent that nurture equates to teaching, such cases show that although such children can learn and indeed perform remarkably, they do not do so in ways their parents or teachers wish, but quite independently, and to internal directions of their own: what you might call natural, rather than nurtured, talent (Badcock and Crespi, 2006).

Another crucial experiment of nature that argues the same case for the ability to be nurtured being determined by a child's nature is Turner's syndrome. Turner's affects 2–3 in 5000 births and some Turner's cases tend to be socially insensitive, easily upset, impulsive and difficult to control, with some diagnosed autistic. Turner's is caused by presence of a single X sex chromosome without the second X that would normally be found in a female or the Y that would be found in a male. A study by David Skuse and colleagues found that suffers whose X came from the mother were much more likely to show autism-like social deficits by comparison to those whose X came from the father (Skuse, 1999, 2000, 2002, 2007; Skuse et al., 1997). Given that family backgrounds of the sufferers were not otherwise much different, the finding argues the same conclusion as autism in general: *nurture via nature*, so to speak.

Monoamine Oxidase A and Antisocial Behavior

An even stronger case for the same conclusion comes from the Dunedin Multidisciplinary Health and Development Study which tracked 1037 children born in New Zealand in 1942 and assessed them at two-yearly intervals, with the original sample 96% intact 26 years later. The study notes that childhood maltreatment increases risk of later criminality by approximately 50%, and that the earlier it occurs, the more likely is it to have this effect. Nevertheless, most maltreated children do not become delinquents or criminals, but the reasons why are not known.

Monoamine oxidase A (MAOA) is an enzyme that degrades neurotransmitters such as serotonin, norepinephrine and dopamine. Disruption of the gene in mice increases concentration of these neurotransmitters along with aggression. Evidence that this gene might be implicated in violent behavior in man was found in a Dutch family where eight male members who had been convicted of assault, incestuous rape, arson, and attempted homicide were found to lack MAOA entirely. Of 442 males in the Dunedin sample, 12% who both were maltreated and had low-activity MAOA accounted for 44% of all convictions for violence in the sample; 85% with low MAOA activity showed some antisocial behavior; 45% of those with high-activity MAOA and maltreatment showed antisocial behavior; and 25% of nonmaltreated were antisocial irrespective of MAOA expression. The authors conclude that

> Maltreated children with a genotype conferring high levels of MAOA expression were less likely to develop antisocial problems. These findings may partly explain why not all victims of maltreatment grow up to victimize others, and they provide epidemiological evidence that genotypes can moderate children's sensitivity to environmental insults.

Conclusion: X-Linkage, Epigenetics, and the New View of Nature and Nurture

Duchenne muscular dystrophy is a classic X-linked recessive disorder that affects approximately 1 in 3500 males and results in muscle wastage, paraplegia, and eventual death. But cases are known in which one of a pair of MZ female twins has the disease, and the other has not. The reason is that because males have only a single X-chromosome, they are effectively homozygous for the disorder, while females, with two Xs, will usually be heterozygous, and protected by the non-Duchenne X. On average, half of the cells in a woman's body express one X, and the other half express the other. But because cell lineages inherit their pattern of X-inactivation from very early precursors during embryonic development, and because the splitting that can result in MZ twins occurs at much the same time, it is possible that one of a pair of such twins may predominantly express just one parental X and the other the other one, explaining the remarkable fact that such female twins can be discordant for this classic genetic disorder (Bainbridge, 2003: pp. 145–154).

There are at least 150 genes linked to intelligence on the X-chromosome, and verbal IQ is definitely known to be X-linked (Goodman and Anderton, 1997). A recent study found that compared to male, female identical twins vary more on measures of social behavior and verbal ability thanks to differential X-inactivation. As a consequence of this, the heritability of intelligence has probably been systematically underestimated (Loat et al., 2008). Indeed, the fact that males have only one X-chromosome to rely on – the one they got from their mother – almost certainly explains not simply why so many more males than females have IQs below 70, but also why 20% more males than females have IQs above 140. Greater variability is inevitable if only one X-chromosome is being expressed as compared with the two on which a woman can normally rely (Lehrke, 1997).

As a result of such findings as these, a recent study of DNA expression profiles in MZ and DZ twins pointed out that "molecular mechanisms of heritability may not be limited to DNA sequence differences." Indeed, the authors speculate that, because identical twins reared together or apart are generally quite similar on measures such as brain-imaging, IQ and other psychometrics, "epigenetic differences between identical twins – in other words, those affecting gene expression – are

much more important than environment" (Kaminsky et al., 2009). And of course, if this is true, it may well be true of many other factors that demonstrably run in families, show high twin concordances, but do not obey classical Mendelian rules of inheritance – most importantly perhaps, mental illnesses such as autism or schizophrenia, where Crespi and Badcock recently proposed a general theory in terms of such epigenetic mechanisms (Badcock and Crespi, 2008; Crespi and Badcock, 2008).

At the very least, these recent findings suggest that Galton – and indeed most other writers on the subject since – was wrong to think that effects of nurture could be assumed to explain any and all differences between MZ twins and that nature explained all the similarities. It now seems that variations in the expression of genes like those found in MZ female twins could also explain observed differences quite independent of any environmental or nurturing factor. Furthermore, the emergence of epigenetics and the discovery of a possible regulatory role for 80% of the nonprotein coding DNA which makes up 97% of the human genome suggests that on the nature side too there remains much to be learnt (Ecker et al., 2012). Indeed, it has been argued that the nature/nurture controversy is itself little more than a cultural expression of more profound genetic conflicts originating in the extreme asymmetry of parental investment in human beings (Badcock, 2000: pp. 262–268).

Abstract

Deep-sea navigation began some 3500 years ago when Stone Age voyagers first began expanding into the Pacific, using naked-eye observations of the stars, winds, ocean swells, and other natural signs to guide their canoes. However, contemporary, science-based navigation developed much later from seafaring traditions practiced around the linked continents of Africa, Europe, and Asia that were initially more oriented toward coastal trade and travel than open ocean sailing. In the fifteenth-century AD Portuguese mariners combined methods from these traditions with new techniques for exploiting global wind patterns to begin sailing beyond long established routes and eventually around the world, which in turn led to the establishment of the first global maritime empires. In following centuries, further application to navigation of astronomy, mathematics, and other disciplines enabled navigators to guide their ships more and more expeditiously and safely to any port in the world, a crucial requirement for the current world system. More recent developments in electronic navigation, now epitomized by the satellite-based Global Positioning System, have brought increasingly greater precision to what long ago began as simple wayfinding. The development of navigation has played a key role in the globalization of the human community, and now provides the means for extending the human reach into space.

'Navigation,' from the Latin *navis*, a ship, and *agere*, to drive, originally referred to the art of sailing a vessel from one point to another, but is now also applied to guiding aircraft and spacecraft. Beginning with early evidence for deep sea voyaging, this article examines the worldwide development of navigation and touches upon the implications for humankind of navigating freely around the globe and into space.

'Navigation,' from the Latin *navis*, a ship, and *agere*, to drive, originally referred to the art of sailing a vessel from one point to another, but is now also applied to guiding aircraft and spacecraft. Beginning with early evidence for deep sea voyaging, this article examines the worldwide development of navigation and touches upon the implications for humankind of navigating freely around the globe and into space.

Early Navigation in the Pacific

Although most accounts of the development of navigation begin with early seafaring in the Mediterranean and the Indian Ocean, recent research points to the Pacific as the region where humans first sailed routinely far out to sea. Around 1500 BC Stone Age seafarers began expanding eastward from island Southeast Asia toward the open Pacific, where, over the next 2500 or so years, they and their descendants discovered and settled all the inhabitable islands of remote Oceania, the vast island world composed of eastern Melanesia, Micronesia, and Polynesia.

Sailing eastward into the ocean was a formidable task as the trade winds blow from the east and inter-island distance increase until they reach more than 3500 km in the far reaches of Polynesia. To accomplish this, pioneering seafarers sailed in outrigger and double canoes, exploited seasonal wind shifts, and navigated without instruments by observing the stars, sun, and other celestial bodies, ocean swells, winds, birds, and other phenomena. They oriented on a conceptual compass of up to 32 points labeled with the rising and setting points of key stars and constellations or the distinctive winds that blew from particular directions. Although they might outline their compass on the ground for teaching purposes, navigators sailed only with its image in mind, along with memorized compass bearings to and from the islands within their voyaging range. They steered on stars and sun when low on the horizon, or on the dominant swells and prevailing wind, all calibrated to their compass points. Their system did not include latitude and longitude, although some navigators may have judged north-south position by what stars passed directly over them, and from the height of Polaris and other circumpolar stars. Progress en route was estimated in terms of the shifting bearings of an unseen reference island off to one side of the course, and other mental plotting methods. To detect land before it could be seen, navigators looked for land-nesting birds fishing out to sea, disruptions in the ocean swells caused by islands, and other signs. That virtually every Oceanic island is part of an archipelago both facilitated discovery of new islands and made navigating between widely separated ones easier. A navigator could make landfall on any island within the chain containing the target island, then reorient toward the final destination.

However, although this Pacific initiative demonstrates that long, navigated voyages can be made without instruments, charts or mathematical calculations, it did not lead to the global, science-based navigation methods employed today.

Navigating Offshore Europe, Asia, and Africa

While canoe voyagers were expanding over the Pacific, other maritime peoples were sailing along the shores of the linked continents of Africa, Europe, and Asia, and to and from adjacent islands. Sea traders and raiders had long sailed in the Mediterranean, the Indian Ocean, and the China Sea. By Roman times – if not before – trade was flowing between the Mediterranean world and China via the Indian Ocean. Judging

from Greek, Arab, and Chinese sources, although much voyaging was coastal, and thus involved navigating primarily by landmarks and soundings, some routes took mariners well away from land, and therefore required at a minimum the ability to sail by steady winds and observations of the stars. Voyages made between Arabia and India by means of alternating monsoon winds provide a case in point.

Deep Sea Navigation and Global Voyaging

Although Herodotus mentioned a Phoenician expedition made around Africa, and much later Viking sailors were able to travel from one island to another across the North Atlantic, regular sailing beyond the linked continents did not begin until the fifteenth-century AD, when the Portuguese developed methods for deep-sea navigation. Early in that century Portuguese mariners began to explore down the African coast, but found that whereas it was easy to sail south with the prevailing northerly winds, tacking back against these was most difficult. Experience gained in sailing to and from the Azores and islands scattered down the African coast had acquainted them with the global winds, the easterly trade winds of the tropics and the westerlies of the temperate latitudes. In sequence, these offered a way to sail back from Africa with fair winds all the way. By heading directly out to sea, these mariners learned that they could sail in a long slant northwest across the easterly trade winds, and, upon reaching the belt of westerlies, could then turn east to sail downwind to Portugal.

However, methods worked out in the Mediterranean for navigating with compass, rudimentary charts, and dead reckoning (estimating position by recording compass heading and distance run) proved inadequate on these long, roundabout crossings. Accordingly, the navigators adapted an astronomical technique for measuring the height of Polaris above the horizon to monitor their progress northward until they were directly west of their destination in Portugal. Before departing from, for example, Lisbon, they marked the altitude of Polaris as seen from that port on a quadrant, a simple instrument for measuring the height of stars above the horizon. (As Polaris was then located about 3.5° from the north celestial pole, with corrections its angular altitude indicated the latitude of the observer.) Then, on the return voyage as they headed west from Africa and then started curving to the north, they watched Polaris rise higher and higher in the sky. Using their quadrant they determined when Polaris had risen to the same height as seen from Lisbon, and then turned east to sail downwind with the westerlies, keeping the Pole Star at the same height in order to reach the port directly.

The crisis caused when, upon crossing the Equator, Polaris dropped below the horizon was resolved in the 1480s. In one of the first examples of a government bringing science to bear on an applied problem, King João II enlisted astronomers, mathematicians, and other scholars to develop a method whereby the height of the sun could be used in place of that of Polaris to determine latitude. With the resultant 'Rule of the Sun,' and tables of the sun's daily position at various latitudes, navigators were able to sail farther and farther down the African coast. In 1497–98 Vasco da Gama sailed in a long arc across the trade winds to the South Atlantic westerlies, then turned east to sail around Africa and up its east coast. From there, under the direction of a local navigator (arguably either an Arab or a Gujerati), he reached India, thereby opening a direct route from Europe to this fabled source of spices, jewels, and other riches.

In 1492 Christopher Columbus used techniques learned from the Portuguese to sail with the trade winds to the Bahamas (which he insisted were outliers of Asia), and then returned by heading north to catch the westerlies. Then in 1522 Juan del Cano brought the *Victoria* back to Spain, completing the first circumnavigation begun by his fallen commander, Ferdinand Magellan. At last the 'world encompassed,' thanks to Iberian seamanship in exploiting global winds and in applying navigational innovations pioneered in other seafaring traditions. For example, a good case can be made that the Chinese developed the magnetic compass, and employed it at sea at least several centuries before its appearance in the Mediterranean in the twelfth century. Furthermore, although the Portuguese use of the height of Polaris to judge progress northward from Africa was a genuine breakthrough, Arab navigators had long before mastered the art of sailing across the Indian Ocean with the aid of Polaris measurements to locate headlands and ports.

Further Navigational Improvements and the World System

The Iberians exploited their maritime achievements by establishing maritime empires, but soon were outgunned and surpassed in both nautical innovation and techniques of colonial exploitation by the Dutch and English. As ship design and seamanship advanced, quantitative navigation evolved through the further application of mathematics and astronomy, and developments in instrumentation and cartography. Astronomical tables multiplied, eventually leading to the publication from 1678 onward of nautical almanacs. Instruments for measuring the altitude of celestial bodies improved, leading to the reflecting octant and sextant in the eighteenth century. Magnetic variation was mapped globally, and improved compasses and ways of measuring distance sailed were introduced, along with charting innovations, including the Mercator projection that enabled mariners to plot long courses with reasonable accuracy.

The last great innovation of this era of sail was the marine chronometer. Whereas navigators could determine latitude, they could only estimate their longitude, resulting in uncertainty, delay, and sometimes maritime tragedy. Because the earth turns on its axis, to determine the longitude of a ship, that is its position east or west of a reference point such as England's Greenwich Observatory, navigators had to keep the time of that reference point. With the development in the late eighteenth century of marine chronometers that could keep time accurately on transoceanic voyages, and their widespread adoption in the nineteenth century, they could at last calculate longitude. The celestial navigation system that had been evolving over the centuries was finally complete. Given clear weather, a navigator could expeditiously and safely direct a ship to any port over the globe. With the conversion from sail to steam, the nautical

means for efficient global maritime trade were in place, and the modern world system erected upon it boomed.

Navigating Electronically

However, the weak point in navigating by magnetic compass, chronometer, and stellar observations remained the changing weather. When clouds, rain, or fog prevented navigators from seeing the stars they had to fall back upon dead reckoning, which, even with instruments for measuring direction of travel and distance run, suffered from cumulative error. Radio direction finding pioneered in the 1910s was an early but only partial solution. However thankful fogbound navigators were to gain radio bearings, these were not very accurate, and available only along the coasts of industrial nations. The first truly all-weather position finding system, LORAN, was developed during World War II for wartime navigation. The reception of synchronized pulses from two pairs of transmitters located at carefully surveyed positions resulted in accurate navigational fixes. The subsequent development of inertial navigational systems was stimulated by further military requirements: guiding missiles and providing bombers and submarines with position information needed for targeting. Employing accelerometers and gyroscopes to determine changes in velocity and direction, these systems provide a continuous indication of position, subject, however, to cumulative error. The most accurate and revolutionary of the electronic navigational technologies is the Global Positioning System (GPS), a US military system made accessible to civilian users, though initially degraded in accuracy. (Russia has its own *Glonass* system.) The GPS system depends upon a constellation of 24 satellites in low earth orbit, which transmit signals that cheap hand-held receivers can process to determine latitude, longitude, and altitude with great accuracy. It was fully operational by the early 1990s, and is now widely used around the world, though not without some misgivings over military control.

Global Navigation and Beyond

Efforts to develop techniques of way finding that began when seafarers first sailed beyond sight of land resulted eventually in a global system of navigation whereby mariners employed the starry points of the celestial sphere to guide their vessels. Now ships, aircraft, and even lone hikers are guided precisely over the globe within an artificial sphere of orbiting satellites. Sophisticated navigational tools also direct robotic and crewed spaceships through interplanetary space, and eventually will be employed to guide them to the stars. Considering the globalizing impacts on human society that have flowed from navigating with increasing accuracy around the planet, thought must now be given to what transformations await humankind as they spread beyond the natal planet.

Abstract

Virtual, computerized spatial navigation tasks have become increasingly popular and important tools for the study of behavioral and cognitive processes involved in spatial navigation and the underlying neural systems. This article provides a broad overview of (1) commonly used virtual navigation tasks, (2) basic behavioral observations relevant to strategies, learning processes, and attention, (3) effects of sex and age, (4) performance in individuals with neurological disorders or brain damage, (5) relationships between measures of brain structure and performance, and (6) findings from functional neuroimaging studies of virtual navigation. The use of virtual navigation approaches in nonhuman animals is also briefly summarized.

Introduction

Three-dimensional computer-generated space, also commonly referred to as 'virtual space,' 'virtual reality,' or a 'virtual environment,' has become an increasingly popular research tool in the experimental investigation of behavioral and cognitive processes involved in navigation and the corresponding neural systems that support these processes. Visual aspects of a virtual environment are typically presented on one or more displays or via a head mounted display (HMD) that can provide the viewer with more immersive experience of the virtual environment. Virtual environments are most commonly rendered from the viewer's perspective (i.e., the first-person perspective); however, third-person perspectives in which the virtual environment is rendered such that the viewer sees an actor (avatar) from a fixed virtual distance and angle are also common. In the case of the first-person perspective the orientation of the viewer can be controlled via a joystick, keyboard, or mouse, or – in the case of HMDs – sensors that detect rotational movement of the head. The term 'virtual navigation' refers to the movement from one location in a virtual environment to another, which can be controlled by the viewer via manipulation of a device (e.g., joystick and keyboard) that results in directional movement within the virtual environment.

Benefits, Appeal, and Limitations of Virtual Navigation in the Behavioral Sciences

The study of navigation by nonhuman animals in mazes and other spatial navigation tasks has a long and rich history in experimental psychology and has been central to research on the neurobiology of spatial behavior and cognition, including contemporary approaches that emphasize the use of spatial navigation tasks to better understand the neurobiology of learning and memory. Since the first studies published in the 1990s, the use of virtual navigation tasks has been increasingly utilized to investigate the behavioral and cognitive processes and underlying neural systems in humans. In addition to allowing laboratory investigations of human navigation, virtual navigation tasks and the virtual environments utilized in them offer other benefits, including excellent control over the visual aspects of the environment, control over how the viewer interacts with the environment, and the ability to compose environments that might otherwise be impractical or impossible to realize in the real world.

The benefits of using virtual navigation tasks do, however, come with some limitations. Perhaps most notably, the lack of realistic movement from one location to another as well as the vestibular, proprioceptive, and haptic (touch) stimulation that accompanies movement is often recognized as a major limitation in generalizing the results of virtual navigation studies to real-world navigation (Taube et al., 2013). Despite these limitations on the range and quality of sensory and perceptual experiences in virtual navigation, the transfer of knowledge acquired in the virtual domain to the real-world has been documented in several reports (Brooks et al., 1999; Foreman et al., 2003). These limitations can also be overcome, for example, through the use of haptic stimulation or immersive environments in which the participant's movements from one location to another in real space are translated to movements in virtual space. It is, further, important to recognize that behavioral and cognitive processes in virtual navigation tasks are genuine processes that reflect the capacities of participants to navigate based on the available information. With the increased use of virtual environments in everyday life and specialized training applications, understanding the behavioral and cognitive processes involved in performance in virtual tasks is an important and challenging undertaking quite apart from the potential generality to real-world navigation processes. Characterization of the basic similarities and differences in the behavioral, cognitive, and neurobiological processes involved in navigation in real and virtual space will be an important topic of study for future research.

Types of Virtual Navigation Tasks

Virtual navigation tasks can be grouped broadly into two categories based on visual content, task demands, and scientific questions: (1) those that attempt to replicate laboratory spatial navigation tasks used in nonhuman animals in the virtual domain and (2) those that attempt to more closely replicate environments encountered by people during typical day-to-day

navigation such as cities or the interior of buildings. Many of the early virtual navigation studies published in the late 1990s involved simulating tasks such as the Morris water task (MWT) for rodents (Morris, 1981). In this task, rodents (typically rats) are placed into a circular pool of cool, opaque water in which a small, hidden (submerged) platform that allows escape from the water is located at a particular spatial location. Visual cues placed in the room beyond the boundary of the pool provide the major source of information used by the animals to swim to the escape platform. Animals that have mastered this task execute more or less direct swims to the hidden platform from multiple start locations and will persist in searching at the platform location if it is removed for a probe trial. The MWT has become the gold standard for measurement of spatial learning and memory in rodents, owing to its simplicity, its unambiguous measurement of spatial navigation, and the clear demonstrations that learning and memory in this task critically depend upon the hippocampus (Morris et al., 1982; Sutherland et al., 1982). Several laboratories have developed and utilized virtual navigation tasks that attempt to capture the important features of behavior, learning, and control of behavior by visual stimuli in the MWT (Astur et al., 1998; Hamilton and Sutherland, 1999; Jacobs et al., 1998; Sandstrom et al., 1998; Gandhi et al., 2007; Piper et al., 2011). The major environmental features of a virtual MWT (VMWT) are a local frame of reference such as a pool or other notional apparatus that includes a conspicuous, visible boundary that provides no disambiguating information regarding spatial location, a hidden goal location (e.g., a hidden platform) that can be made visible to provide a visual cue co-localized with the goal, and a constellation of conspicuous visual cues in the virtual space beyond the apparatus boundary that provide information that can be used for spatial localization and orientation. An example view and layout of a VMWT are shown in **Figure 1**.

The popular radial arm maze (RAM) has also served as a model for virtual navigation tasks that measure reference and working memory in the spatial domain (Astur et al., 2004; Bohbot et al., 2007; Braun et al., 2012). In a typical RAM or virtual RAM (VRAM) there are eight arms that extend out from a central platform, half of which have some item of value to the participant at the end of the arm (e.g., food in the RAM and points in the VRAM), while the other arms hold nothing of value. The maze remains in the same position and orientation relative to visual cues beyond the maze, so the participant can learn to navigate to the locations where there are items of interest and avoid empty arms over the course of training. This type of learning and memory is commonly referred to as 'reference memory,' whereas keeping track of which arms have been visited during a trial is considered a 'working memory' component of the task. The time required to complete a trial and the number of errors (entries into empty arms) are measured. An example view in a VRAM and layout are shown in **Figure 2**. Mazes that require turns at choice points ranging in complexity from the relatively simple T-mazes to mazes with multiple choice points have also been employed (Grön et al., 2000; Moffat et al., 1998; Shore et al., 2001; Baker and Holroyd, 2009; Schmitzer-Torbert, 2007). Canovas et al. (2008) also developed a hole board comparable to its rodent counterpart in which participants must locate multiple rewards among a set of possible goal locations. Virtual navigation tasks have also been utilized to assess learning about geometric features of an environment (Redhead and Hamilton, 2007, 2009; Wilson and Alexander, 2010, 2008). All of these tasks share in common the use of first-person perspective and three-dimensional presentation to simulate viewing real space, and that they were designed to measure performance in tasks that attempt to closely mirror common laboratory tasks. Virtual environments that represent real-world settings such as cities or interiors of buildings are also commonly used to either train participants to navigate in a particular environment or to evaluate navigation in a situation that more closely mirrors commonly utilized navigation skills and strategies in a real-

Figure 1 The virtual Morris water task environment. Panel (a) depicts an aerial view of the virtual environment, with the four vertical walls flattened. The circular pool is positioned in the center of the room. The hidden platform is shown as a black square within the pool. Panel (b) is a first-person view of the virtual environment that would be presented to the participant.

world setting (Brooks et al., 1999; Maguire et al., 1998; Spiers and Maguire, 2007b; Thibault et al., 2013; Wilson et al., 2004).

Psychological Aspects

Navigation Strategies, Behavior, and Cognitive Processes

A number of studies have utilized virtual navigation tasks to investigate the strategies used by humans to navigate under various stimulus conditions and task demands. The conceptual dissociation between allocentric – (world-based) in which the viewer is thought to possess a representation of the external world in which the topographical relationships among the features of the environment are maintained – versus egocentric – (self-based) strategies in which the individual executes movements by way of reference to one's current position or orientation has been widely utilized in research on spatial navigation. In particular, the clearly established link between allocentric navigation and the hippocampus has been a major driving force in the literature on the neurobiology of spatial navigation and spatial cognition (O'Keefe and Nadel, 1978; Knierim and Hamilton, 2011). Accordingly, a considerable amount of research using virtual environments has been aimed at better understanding allocentric navigation, or navigation to a particular location based on its spatial relationship to visual cues, heretofore referred to as 'place navigation.' A variety of distinct behavioral and cognitive processes associated with orientation in the spatial domain have been postulated and measured in virtual navigation tasks (Arnold et al., 2013; Hamilton et al., 2009). With respect to behaviors controlled by external stimuli, place navigation is commonly contrasted with 'cued navigation' (navigation to a location based on the presence of one or more cues located at that location), which can be classified as a form of 'simple guidance,' or 'complex guidance' if sequences of simple guidance responses are involved. 'Response strategies' as in egocentric navigation or selecting movements based on the directional left/right response to be made relative to one's current position, and more recently 'directional responding' (moving in the direction of a goal location by selecting an orientation based on visual features of the environment) are also contrasted with place or allocentric navigation strategies.

An early study by Jacobs et al. (1998) found that participants utilized the topographical relationships between visual cues in the distal room environment in a task similar to the VMWT. Astur et al. (1998) characterized the performance of young university students in a VMWT and noted that many participants took more or less direct trajectories to the goal location from multiple release points and would persist in searching at this location if the goal was removed for a probe trial, consistent with use of a spatial or place navigation strategy, in which the available cues are used to guide navigation to a particular location in the environment. In a VMWT some participants adopt non-spatial strategies that involve non-direct paths to the goal that often include systematic searching of the environment until the goal is encountered (Hamilton et al., 2009). Such strategies usually involve navigating based on features of the local (apparatus) reference frame provided by the circular boundary of the pool that provide no disambiguating spatial information to guide navigation. For example, a participant may learn that the goal is located at a particular distance from the boundary of the local reference frame and perform a circuitous swim around the apparatus at the appropriate distance from the boundary until the goal is encountered.

Hamilton et al. (2002) composed a VMWT in which access to some regions of the virtual pool was restricted such that the participants could not navigate through some regions of the environment, while they could see the entire environment. These authors found that lack of experience in navigating through a region of the environment on a trajectory to the goal location disrupted later navigation through the restricted regions. The authors suggested that familiarity with the views experienced while navigating was important for accurate performance. The results were also highly similar to those observed in rats by Sutherland et al. (1987) using similar manipulations, suggesting a basic similarity in these species in responses to manipulation of distal visual cues in their respective tasks.

A variant of the VMWT in which the goal location is made visible allows for measurement of 'cued navigation' which is

commonly utilized to assess navigation when a spatial strategy is not required and is not the most efficient strategy to support navigation to the goal. Chamizo et al. (2003) employed a VMWT in which both distal room cues and a cue co-localized with the goal were present simultaneously and found a reduction in performance when the cue marking the goal was removed for a test trial, requiring the participant to navigate using the distal cues. That is, the presence of a cue at the goal interfered with learning about the distal cues, a phenomenon referred to as 'overshadowing.' Similar virtual navigation tasks have been utilized to determine whether other types of spatial information such as geometries formed by the apparatus or room are also interfered with or are impervious to the presence of cues that support non-spatial or non-geometric strategies (Alexander et al., 2009; Redhead and Hamilton, 2007, 2009; Redhead et al., 2013; Wilson and Alexander, 2008, 2010). Although the pool in the VMWT is circular and, therefore, does not provide information capable of disambiguating spatial location, Hamilton et al. (2009) hypothesized that the frame of reference provided by the boundary of the pool was, nonetheless, an important determinant of behavior. These authors systematically reduced the height of the pool boundary (ranging from a typical height as shown in **Figure 1** to completely invisible) and found that performance systematically declined as the height of the pool boundary was reduced. One conclusion offered by these authors was that the distal cues disambiguated the otherwise spatially ambiguous pool reference frame, and as the signal provided by the latter frame of reference was reduced, the performance declined as well. Importantly, these findings also indicate that distal cues are not sufficient for spatial navigation in the VMWT, as the reduction in the height of the boundary also reduced the degree to which the distal cues were obscured by the boundary.

Attention

Several groups have integrated virtual navigation tasks with eye-tracking technology to investigate how attention to visual features of the virtual environment, as assessed via gaze measurements, is related to strategy selection or performance. Mueller et al. (2008) used a VMWT to examine sex differences in visual sampling of the virtual environment in relation to sex differences in strategy selection. Eye-tracking data were obtained during the initial portion of the trials in which participants started at several distinct locations in the virtual pool. Males tended to visually sample more of the virtual space than females, who had longer gaze durations directed at particular locations or cues. Livingstone-Lee et al. (2011) also examined visual gaze during the initial portion (1 s) of each trial and observed that attention to the available cues indicated which of two strategies a participant would employ during the trial. Using a VMWT Hamilton et al. (2009) recorded gaze location throughout each trial while participants navigated to a hidden goal and characterized attention to distal visual cues and the local apparatus (pool) boundary by university students who either learned to solve task using a spatial strategy or who adopted a non-spatial strategy. Participants who adopted a spatial strategy initially looked at distal cues and then shifted their attention to the precise location in the pool to which they were navigating for the remainder of the trial. The authors suggested that initial orientation was based on distal visual cues while goal-directed navigation was based on local apparatus features, comparable to shifts that occur during active navigation by rats in the MWT when both local and distal cues are available (Hamilton et al., 2004). In contrast, participants who adopted non-spatial strategies tended to keep their gaze restricted to the region within the pool boundary with little sampling of distal visual cues and no particular focus of the gaze toward any particular location. Andersen et al. (2012) combined eye-tracking with an eight-arm VRAM and found that females spent more time visually sampling landmarks compared to males, while male sampling of visual landmarks decreased with experience. Because information about visual attention can be gathered as individuals navigate in virtual environments, the merging of these technologies will likely play an important role in future investigations concerned with characterizing how visual information is utilized in the service of navigation and how attention to visual information in the spatial domain is influenced by stimulus parameters and modified by experience.

Sex Differences and Aging

Sex differences in spatial abilities have been well characterized and with the advent of virtual navigation tasks several studies have assessed sex differences in ability and strategy selection. Astur et al. (1998) reported a large sex difference in place navigation using a VMWT, with males performing better than females. Driscoll et al. (2005) found that males outperformed females in a VMWT even well into adulthood (>60 years) and that this sex difference across the lifespan was partially explained by circulating levels of testosterone. Mueller et al. (2008) also reported that males performed better than females in a VMWT and, as described in the previous section, tended to sample a larger range of the virtual space as assessed via eye-tracking. One possibility noted by these authors is that males may simply choose to use a spatial (allocentric) strategy more than females. Sandstrom et al. (1998) utilized a similar virtual navigation task and found that females tended to rely on using landmarks while males utilized both geometric features of the environment as well as landmarks. Woolley et al. (2010) used a VMWT and found that the most robust sex difference was evident in the accuracy of the initial trajectory to the goal, whereas only a nonsignificant numerical difference was observed for measures of search behavior. Sex differences have also been observed in complex virtual mazes. Moffat et al. (1998) found that males learn to complete a complex, multiple choice-point virtual maze faster than females and commit fewer errors. Cimadevilla et al. (2011) also reported that males performed better than females in a virtual labyrinth maze. van Gerven et al. (2012) utilized a VMWT in which both place navigation or an egocentric strategy were equally effective for solving the task and found that females adopted a spatial strategy at a higher rate than males. Quantitative measures of performance such as latency to locate the goal or persistence in searching during a probe still favored males, leading these authors to conclude

that sex differences observed in virtual navigation tasks may be more a matter of efficiency in performance rather than strategy selection. One possibility is that differences in experience playing video games that utilize virtual space may contribute to sex differences (Astur et al., 1998; Hamilton et al., 2002). Some studies have also failed to detect sex differences in a VMWT in the same university population that yielded robust sex differences in earlier studies (Hamilton et al., 2009), which might reflect a narrowing of this experience gap.

Several studies have also examined the relationship between aging and performance in virtual navigation tasks. Driscoll et al. (2003, 2005) reported deficits in spatial learning in a VMWT in older adults (60–85 years) compared to younger adults (20–59 years). These age-related declines were accompanied by decreases in hippocampal neurometabolites and volume as well as circulating levels of testosterone. Similar deficits in virtual spatial navigation with age were observed by other groups using a VMWT or comparable task (Iaria et al., 2009; Laurance et al., 2002; Moffat and Resnick, 2002).

Neural Aspects

Virtual Spatial Navigation in Patient Populations

The well-established dependence of spatial navigation in rodents, as in the MWT, on the hippocampus and related circuitry (Sutherland et al., 1982; Morris et al., 1982) motivated several laboratories to examine the performance of patients with damage to medial temporal lobe structures in virtual spatial navigation. Amnesic patients with medial temporal lobe resections are impaired in the VMWT (Astur et al., 2002; Goodrich-Hunsaker et al., 2010) and a VRAM (Bohbot et al., 2004; Goodrich-Hunsaker and Hopkins, 2010). Bartsch et al. (2010) subsequently demonstrated deficits in a VMWT in patients with focal damage to the CA1 subfield of the hippocampus. A number of laboratories have also reported deficits in virtual navigation tasks in patient populations in which hippocampal pathology provided the motivation to evaluate place learning and navigation in these populations. These include deficits in schizophrenic patients (Hanlon et al., 2006), individuals with traumatic brain injuries (Skelton et al., 2000), children with fetal alcohol syndrome (Hamilton et al., 2003), patients with unilateral or bilateral vestibular failure (Brandt et al., 2005; Hüfner et al., 2007), temporal lobe epileptics (Cimadevilla et al., 2011), pediatric anxiety patients (Mueller et al., 2009), individuals with depression (Cornwell et al., 2010), and individuals with posttraumatic stress disorder (Tempesta et al., 2012).

Virtual Navigation and Structural Neuroimaging

Several studies have linked structural measurements in brain regions involved in real-world navigation and performance in virtual navigation tasks. Driscoll et al. (2003) reported a strong positive correlation between time spent searching at the goal location during a no-platform probe trial in the VMWT and hippocampal volume. Iaria et al. (2008) also reported that navigation performance in a virtual environment is related to structural features of the hippocampus. Using diffusion tensor imaging (DTI) these authors found that individuals with high fractional anisotropy, a measure of axonal density and myelination, in the right hippocampus, were faster at constructing a map-like representation of the virtual environment and better at using this information to orient. Hippocampal atrophy related to vestibular loss has also been linked to poor spatial performance in the VMWT (Brandt et al., 2005). Segmentation analyses of gray matter density have also been correlated with strategy selection. In a VRAM Bohbot et al. (2007) found that individuals who adopt a spatial strategy had higher levels of gray matter in the hippocampus and lower levels of gray matter in the caudate nucleus compared to individuals who adopted strategies that involve navigation based on individual cues. Evensmoen et al. (2013) also found that volume of specific hippocampal subregions varied with the resolution of an individual's spatial representation of a virtual environment, with more coarse representations correlated with anterior hippocampal volume and more fine-grained representation associated with posterior hippocampal volume. Correlations between performance in a VMWT and gray matter in the inferior parietal lobule have also been observed in preadolescent males (Mueller et al., 2011).

Virtual Navigation and Functional Neuroimaging

Neuroimaging experiments have consistently yielded evidence that the hippocampus, parahippocampal gyrus, and parietal cortex are engaged during virtual spatial navigation. In an early fMRI investigation of virtual navigation Aguirre et al. (1996) scanned participants while they navigated in a series of virtual corridors and observed increased activation of parahippocampal cortex bilaterally. In a positron emission tomography (PET) study Maguire et al. (1998) found that exploration of virtual rooms that contain salient landmarks result in increased activation of the right parahippocampal gyrus compared to rooms devoid of conspicuous landmarks. Aguirre and D'Esposito (1997) also demonstrated that the parahippocampal region is recruited when participants are asked to recognize a location in a virtual city or select the direction of another location. The inferior parietal cortex was activated to a greater degree in the direction selection task than the recognition task, an observation consistent with the distinction between spatial localization as in an allocentric strategy and orientation/trajectory selection. Spiers and Maguire (2007a) reported dissociation between egocentric direction and distance to locations in an fMRI experiment, with the former correlated with parietal cortex activation and the latter positively correlated with frontal cortex activity and negatively correlated with the activity in the subiculum and entorhinal cortex, the major neocortical input to the hippocampus. Grön et al. (2000) measured brain activation with fMRI while males and females navigated in a maze that included multiple choice points. Both males and females displayed activation of right hippocampus, parahippocampal gyrus, and parietal cortex. Males displayed higher levels of activation in the left parahippocampal gyrus and left hippocampus, whereas females displayed higher levels of activation in the right parietal and right frontal cortices. These authors reasoned that the observed differences reflect sex differences in strategy selection, with females relying

more on landmarks than geometric features of the environment (Sandstrom et al., 1998).

Iaria et al. (2003) found that participants who used spatial information provided by configurations of landmarks displayed increases in hippocampal activity, whereas following more extensive experience participants who utilized non-spatial strategies displayed sustained activity within the caudate nucleus, an aspect of the basal ganglia implicated in well-established behavioral responses and habit. Bohbot et al. (2004) similarly found that the use of a spatial strategy resulted in increased hippocampal activity, whereas the use of a simple response strategy resulted in an increased activity in the caudate nucleus. Doeller et al. (2008) used a circular arena surrounded by cues, similar to the configuration of a VMWT, but which also contained local landmarks, to dissociate brain regions involved in navigation based on boundary features of an environment and landmarks. Boundary information was associated with hippocampal activation whereas landmark processing was related to activity in the dorsal striatum, which includes the caudate nucleus. Evensmoen et al. (2013) reported dissociations between anterior and posterior hippocampus based on whether participants possessed a local, fine-grained, or global, coarse, representation. Anterior hippocampal activity was associated with global representation of the virtual environment whereas posterior hippocampal activity was related to both local representation of the environmental features and the use of non-spatial strategies. The common regions activated during virtual navigation, namely the hippocampus, parahippocampal gyrus, and parietal cortex have also been shown to display decreased activation in elderly individuals compared to young participants during virtual navigation (Moffat et al., 2006).

In the rat, movements related to navigation from one location to another are associated with low-frequency oscillations in the 3–15 Hz (rhythmic slow activity) or theta (~4–8 Hz) range, which has been linked to processing of spatial information during active navigation (Okeefe and Recce, 1993). Kahana et al. (1999) recorded electroencephalograms (EEGs) from depth electrodes implanted in the hippocampi of epileptic patients while they performed a virtual navigation task. Theta activity in the temporal cortex was elevated in more complex virtual mazes. Cornwell et al. (2008) recorded magnetoencephalography (MEG) signals while participants navigated in a VMWT and found increased theta activity in the left hippocampus during performance of the VMWT compared to a task that did not involve goal-directed movements. These observations indicate the possibility of a basic similarity between the role of low-frequency oscillations in rats and humans during performance of real and virtual navigation tasks (O'Keefe and Burgess, 1999; Watrous et al., 2013).

Collectively, the available data on the role of the hippocampus and related structures in human virtual navigation is highly consistent with data from rodent studies showing that place navigation is impaired following hippocampal damage, and the existence of hippocampal place cells that fire selectively when the animal is in a particular location in an environment (O'Keefe and Dostrovsky, 1971). More recently, the so-called 'grid cells' in the medial entorhinal cortex, a major neocortical input to the hippocampus, have been described in rats, bats, and monkeys. Grid cells fire at regular spatial intervals as an animal moves through an environment such that when recorded over a long period of exploration, the spatial plots of firing rates are organized in a grid (Hafting et al., 2005). One possibility is that these cells provide information about the spatial scale of movements and location within an environment based on both internal and external cues. Jacobs et al. (2013) found cells in patients implanted with depth electrodes that display grid-like firing rate properties when participants were performing a virtual navigation task. Jacobs et al. (2010) also characterized a population of entorhinal cortex neurons that selectively coded for the direction of movement in a virtual environment, which is consistent with observations in rats showing that some grid cells have directional firing properties (Sargolini et al., 2006). Collectively, these observations indicate that many aspects of the neural bases of navigation characterized using invasive studies in rodents are also observed in humans at various levels of analysis.

Virtual Navigation in Nonhuman Animals

Among the major considerations that contribute to the appeal of using virtual navigation technology is the capacity to measure spatial navigation in humans in a laboratory setting. Other appealing features of virtual navigation tasks such as increased control over environments and the ability to compose environments in numbers or scope that would be impractical, however, would also be beneficial in studies that examine navigation in nonhuman animals. Several laboratories have utilized virtual environments to examine navigation by monkeys (Furuya et al., 2014; Hori et al., 2005, 2003; Sato et al., 2004; Washburn and Astur, 2003), allowing for the simultaneous recording of individual neurons during virtual navigation. For example, Furuya et al. (2014) found that neurons in the parahippocampal gyrus showed reliable responses across three environments in which the scaling of the environment was manipulated in relation to the distal visual cues, while neurons in the hippocampus showed reliable place responses across environments. In both regions, the firing properties of the neurons were modified based on environment scale, with reductions in scale associated with reductions in the size of place fields. Virtual navigation tasks have also been utilized in non-primates. Miyata and Fujita (2010) trained pigeons to follow routes based on optic flow information provided via an LCD display. Virtual navigation tasks have also been used successfully in rats (Holscher et al., 2005; Youngstrom and Strowbridge, 2012) and mice (Dombeck et al., 2010; Harvey et al., 2009). The use of virtual navigation tasks in nonhuman animals will allow for comparative analyses that are less confounded by differences between real-world and virtual navigation, and for recordings of individual neural activity during ongoing behavior to be characterized and incorporated with the rich literature on individual neural activity during real-world navigation in standard laboratory tasks. Such studies will provide information about the basic differences between real-world and virtual navigation crucial for

understanding the limitations on generalizations that can be made from results obtained in virtual navigation tasks.

Nazi Law

Hubert Rottleuthner, Free University of Berlin, Berlin, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Following the exposition of two basic principles of the Nazi state and law – the leader principle and the people's community based on racial homogeneity – the development of Nazi law within three dimensions of a legal order is described: legislation in public, penal, and civil law; the legal staff; and the societal legal culture. Nazi law can be characterized by (1) a permanent combination of normal routine and terror culminating in the Holocaust, (2) a mixture of modernity and regression, and (3) morally laden concepts that were used to justify every legal measure and illegal ones as well. Finally, one can ask whether there was a 'legal order' at all during the Nazi era.

It would not be appropriate to look at Nazism only in light of the Holocaust, without considering everyday law and the administration of justice. It is important not to neglect the routine work, the 'normality' of the judicial system with its millions of cases and unpublished decisions. A high degree of normality, of daily routine, is indispensable in such a system in order to secure the conformity of the legal staff, while continuous intervention would lead to a feeling of uncertainty.

The term 'Nazi law' could refer broadly to all legal norms and court decisions that were issued in Germany during the Nazi era between 1933 and 1945. In a narrow sense, Nazi law means only those norms and decisions that can be interpreted as an expression of basic principles of a crude Nazi ideology.

Basic Principles

The basic Nazi principles of the organization of law and state can be characterized by an ambivalent juxtaposition of the leader principle (*Führerprinzip*) and a racial–ethnic substance of the people's community (*Volksgemeinschaft*). On the one hand, we find the 'Führer' as the head of a unitary, authoritarian, and militaristic state whose decisions are law. On the other hand, we have the homogeneous nation of the German people. On the political level, there is no separation of powers, no federal structure, only one party; hence there is no democratic, parliamentary, and pluralistic struggle for power. The leader acts beyond the ligatures of the rule of law. On the societal level, class struggle is replaced by racial integration. Foreign elements – non-Aryans, political enemies (such as communists and social democrats), 'asocial' people, criminals, and so on – are excluded by legal measures, by eugenic procedures, or by the arbitrary power of the police and the *Schutzstaffel* (SS). The common good is authoritatively defined according to the 'sane feeling of the people' (*gesundes Volksempfinden*). The distinction between state and society, the boundaries between public and private, are dissolved by the totalitarian equalization and unification (*Gleichschaltung*) of intermediary organizations such as parties, trade unions, the media, universities, and the arts (only the churches could maintain some kind of relative autonomy). This system of paradoxical 'substantial decisionism' collapsed after its belligerent expansion.

Legislation

On the ideological level of legal philosophers, legislation was understood – and in fact it was a misunderstanding of Savigny's notion of the *Volksgeist* – as the 'expression' of the popular substance, that is, of a homogeneous *Volksgemeinschaft*. But how did the 'law on the books' come into the books in the first place? Legislative products, even during the Nazi era (1933–45), reflected a compromise of conflicting forces. So one has to look behind propaganda and find out how they came into being. There exist only a few studies on the origin of Nazi legislation, for example, in the field of marriage law, labor law, and the law against the misuse of legal advice.

In terms of legislative activity in Nazi Germany, a huge amount of routine work was done after 1933. There were not only the Nuremberg Laws (of 15 September 1935), including the 'law for the protection of German blood and German honor' (*Gesetz zum Schutz des deutschen Blutes und der deutschen Ehre*) and the 'Reich citizenship law' (*Reichsbürgergesetz*), but also regulations concerning chimney sweeps, seeds, and wine corks.

The height of legislative regulation in twentieth century Germany – as far as the number is concerned – was reached between 1938 and 1939 (they were mainly measures to prepare for a war economy); this finding might be of interest for those who talk about today's 'regulation flood.' This vast amount of legislation indicates an instrumental use of norms, not an expression of a *völkische* (racial–ethnic) will as a fundamental principle of Nazi ideology. As far as the forms of regulation are concerned, we find a variety of norms ranging from traditional laws to single orders of the Führer, sometimes circulated via radio broadcasts, and even unpublished ones like the command of September 1939 to start the euthanasia program.

Public Law

After 1933 it was an open question whether the Weimar constitution (drafted in 1919) was still valid. Although it was

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86085-7

never formally invalidated, it was displaced by new 'basic laws,' including the program of the Nazi Party. Basic rights were eliminated through the *Verordnung des Reichspräsidenten zum Schutz von Volk und Staat* of 28 February 1933. There was no separation of powers after the *Ermächtigungsgesetz* of 24 March 1933, which empowered the government or single ministries and other authorities to issue laws. The federal structure of the Weimar Republic was destroyed. Political power was centralized in the Reich authorities with Hitler on top as the Führer and Reichskanzler in one person after 1 August 1934. The will of the Führer was the supreme and unlimited source of law. His will could be manifested in a variety of norms (*Gesetz, Verordnung, Erlaß, Einzelbefehl, Gesamtauftrag*, etc.). Below the level of the Führer there existed no clear competences, but rather a structural chaos that has been labeled a polycratic regime.

Penal Law

In penal law the principle of *nulla poena sine lege* (no punishment without a law) was abandoned by introducing the 'analogous' application of the law according to the *gesundes Volksempfinden*, and replaced by the principle of *nullum crimen sine poena* (no crime without a punishment). Various retroactive laws were issued. The penal system no longer focused on the criminal act defined as an offense against the *Volksgemeinschaft*. Instead the 'types' of the criminal (*Tätertypen*) became important. There was the *Gewohnheitsverbrecher*, the habitual criminal against whom the Nazis introduced the 'three strikes rule' with capital punishment as an obligatory sanction after 1941; the violent criminal (*Gewaltverbrecher*); the murderer as a distinct type (*Mörder*); and the 'people's blight,' a person like a pestilential insect that has to be exterminated (*Volksschädling*). Instrumental use of penal law such as the 'war-time penal code' (*Kriegssonderstrafrechtsverordnung*) (1939), or in its extreme instance the so-called penal code for Poles (*Polenstrafrechtsverordnung*) (1941), became normatively unlimited. It is characterized by extremely vague norms that confer broad judicial discretion, and by a terroristic severity of sanctions.

Civil Law

In civil law there were only minor changes in the legislation, except in agricultural law, family law, and labor law. Using old rules, the judiciary invented new doctrinal formulas that enabled the judges to intervene in the formerly private sphere of autonomous individuals by the interpretation of a contract as a *Gemeinschaftsverhältnis* (relationship of a community, an organic union). Through the 'law ordering national labor' (*Gesetz zur Ordnung der nationalen Arbeit*) of 20 January 1934, the autonomy of trade unions and employer organizations to reach collective agreements was abolished. Strikes were illegal. The collective actors were integrated in the *Deutsche Arbeitsfront* and put under the control of state executors. The worker became a popular figure of Nazi propaganda, while the labor market, including wages and mobility, was intensively regulated long before World War II. In other spheres of the economy, the state favored the interests of factions of big business and their trusts; state intervention increased during the war.

The Legal Staff

During the first years after 1933, court organization was not substantially changed. Special courts (*Sondergerichte*) (1933), the *Volksgerichtshof* (1934), the *Reichskriegsgericht* (1936), and the *Reichsverwaltungsgericht* (1941) were established. Under the new regime, about 15% of judges and prosecutors were dismissed on political and/or racial grounds. For various reasons, the caseload decreased. A substantial change took place in the form of *Verreichlichung*, that is, the centralization of the court administration under the department of justice of the Reich that after 1935 controlled the jurisdiction of the courts. After 1936, the judiciary lost its competence in 'political' issues (mainly matters concerning the secret police). In an agreement, with the ministry of justice in 1937, the Gestapo gained permission to torture (*verschärfte Vernehmung*). Step by step the courts were excluded from prosecuting and sentencing Jews, homosexuals, and other enemies of the German *Volk*. In an agreement between Thierack (Minister of Justice) and Himmler (Chief of the Police and of the SS, respectively) of September 1942, 'asocial elements,' Jews, gypsies, Russians, Ukrainians, and so on, had to be handed over from the prisons to Himmler's myrmidons.

All these measures were executed, accepted, or tolerated by members of the legal staff. A basic problem in dealing with Nazi law is how to explain the degree of conformity among judges, prosecutors, attorneys, and legal scholars. One explanation given after 1945 (Radbruch, 1946) was that they acted on the basis of a 'positivistic' attitude by simply adhering to the law. Instead, it was a positive attitude to the new regime that was hailed by the organizations of judges and prosecutors. Judges were overzealous in their duty, as in dismissing Jews from their legal positions as employees or tenants. Faced with the atrocities against Jews and political opponents, they displayed a passive onlooker's attitude. Courts used racist arguments without being obliged to do so. They imposed excessively severe sentences: estimates of the number of executions, including those imposed by military courts, range from 20 000 to 50 000. There was almost no judicial opposition; instead there was widespread voluntary obedience. The explanation that legal positivism was responsible for the conformity of the legal staff is no longer accepted today.

Legal Culture

There exists very little evidence about 'legal culture,' in the sense of knowledge and opinions about law among the populace, during the Nazi era. Systematic examination of facts that illustrate people's attitudes toward legal norms, judgments, legal institutions, and professional groups does not reveal a homogeneous *Volksgemeinschaft*, but a variety of differing opinions and attitudes. Many findings, such as reports by the *Sicherheitsdienst* of the SS, indicate that a deeply rooted trust in

the courts (and in the Nazi regime in general) persisted until 1945.

Generally, only a small fraction of social problems or conflicts reach courts; criminal prosecution and private invocation of the courts are extremely selective, so it is significant for the Nazi era that a considerable portion of the activities of the Gestapo was instigated and supported by private informers.

Normality and Terror

An essential feature of the Nazi regime was the combination of open terror and everyday routine. Legally 'normal' and terrorist measures alternated, and terrorism occurred under the guise of the 'normal.' Three events exemplify this alternating dance between terrorism and normality:

1. The murders of Röhm (the leader of the *Sturmabteilung* (SA)) and his followers in June and July 1934, which was followed by doctrinal justification (in particular by Carl Schmitt, at that time a professor for public law in Berlin), as an act of government self-defense.
2. The elimination and extermination of persons of so-called inferior quality, starting with the 'law on the prevention of offspring afflicted with a hereditary disease' (*Gesetz zur Verhütung erbkranken Nachwuchses*) of 14 July 1933 (introducing coercive sterilization), followed by the 'law on the protection of the hereditary health of the German people' (*Gesetz zum Schutze der Erbgesundheit des deutschen Volkes*) of 18 October 1935 (preventing marriage in the case of certain diseases), and finally the transition to secret euthanasia actions, authorized by Hitler, started in January 1940.
3. The legal persecution and finally the extinction of Jews, which had been ideologically and administratively prepared by cumulative anti-Semitic legal regulations as well as nonlegal measures.

The mixture of normality and terror, together with strong elements of continuity, helps explain the high degree of conformity among the legal staff as well as among the general populace.

Law and the Holocaust

The legal persecution of Jews advanced step by step, interrupted and radicalized by brutal, direct measures. First came the 'law for the reconstitution of officialdom' (*Gesetz zur Wiederherstellung des Berufsbeamtentums*) of 7 April 1933, excluding Jews – with a few exceptions – from the civil service. The concept 'Jew' was not defined according to criteria of race; instead the religion of the grandparents was adopted as a criterion that could be easily used administratively. Step by legal step, the scope of social activities and the positions available to Jews were reduced. In September 1935 (through the Reich citizenship law) Jews were denied full citizenship. The new crime of '*Rassenschande*' (prohibition of sexual intercourse between Jews and non-Jews) was introduced (in the 'law for the protection of German blood and German honor'). Legal 'aryanization' of Jewish property and exclusion from professions were pursued continuously by the legislators. The yellow star (*Judenstern*) was introduced in September 1941. In December 1941, Poles and Jews in the occupied territories in Eastern Europe were put under special penal regulations, with the threat of capital punishment for almost every kind of disobedience. After the January 1942 Wannsee Conference, at which the plans for the extermination of the Jews were formulated, their further persecution and extinction was by no means carried out extralegally but in a legal–bureaucratic manner. From 1 July 1943, crimes committed by Jews were persecuted and sanctioned by the police only, and no longer by courts. The last published formal directive, of 11 November 1944, barred Jews in Berlin from using heated public rooms.

Apart from this kind of legally sanctioned persecution, there were repeated 'wild' actions, starting with the anti-Semitic excesses in March and April 1933. Such persecutions reached their first climax in the anti-Semitic pogroms in November 1938, followed by a legal sequel (obligation to pay a tribute; collection of insurance benefits). The same pattern holds for the legal exclusion of other victims of Nazism: Sinti, Roma and other *Fremdvölkische*, homosexuals, criminals, the insane, asocials, communists, social democrats, Jehovah's Witnesses, and so forth.

Injustice did not arise all of a sudden, but gradually. The step-by-step character of the persecution of people not belonging to the *Volksgemeinschaft* contributed to the high degree of conformity among the legal staff. By accepting the first steps, officials became unable to resist the further steps, even though those might have seemed unjust.

Hitler and the Law

The remarks about law in Hitler's *Mein Kampf* indicate a purely instrumentalist understanding of law's function in society: law is deprived of any intrinsic value and only conceived as an instrument to promote the Aryan race, to suppress and exclude all kinds of enemies, and to secure the life of the German people. A few deprecatory remarks made by Hitler about jurists are reported. Sometimes he intervened arbitrarily in court cases, most famously in the Schlitt case (in 1942), which he used to have himself declared – for the second time after the Röhm murders – the supreme judge. After 1942 he was no longer concerned with individual cases.

Continuity and Discontinuity, Modernity and Regression

The Nazi era must neither be seen as entirely continuous with or totally isolated from what came before and what happened afterward, that is, its Weimar prehistory and the coming to terms with Nazism after 1945. The moments of continuity include both personnel and substantive factors. Personnel issues include the continued activity – and loyalty – of most lawyers within the judiciary and among legal scholars before and after 1933 as well as (at least in the Western zones of Germany) after 1945. During the last decade, a couple of studies were published concerning the postwar continuity of organizations, state institutions, and big firms that were

involved in the exploitation of forced workers during World War II. Data on career patterns of higher members of the legal staff before and after 1945, revealing a high degree of continuity, were collected and analyzed (Rottleuthner, 2010). Monographs deal with prominent Nazi legal scholars like Carl Schmitt, Ernst Forsthoff, and Karl Larenz, who after 1945 disguised their Nazi past in a cloud of silence.

Substantively, in the legal domain the Nazis and their legal lackeys were not very inventive. With the possible exception of agricultural law – and after 1939 the regulations concerning the war economy – they retained the traditional legal corpus. The vast majority of legal norms remained valid after 1933, but they were given new interpretations. In large measure they continued trends that had been evident before 1933, such as in penal law. With regard to eugenics, too, the Nazis referred back to much older concepts and also claimed to rely on similar practice abroad, for example, in the United States and Scandinavia. In civil law, too, one can find continuity, as in the so-called 'materialization' tendencies in private law, that is, the limiting of contractual autonomy.

In some areas, the Nazi period achieved solutions for old disputes, as in the corporation act (*Aktiengesetz*) of 1937. From a wider historical perspective some reforms can be interpreted as 'progressive': protective regulations concerning pregnancy and motherhood as well as juvenile workers, regulation of working hours, and so on. In divorce law (1938), the grounds for divorce were broadened from the guilt of one spouse to include marriage breakdown (this again was an idea dating from before 1933). An innovation in legal doctrine was E. Forsthoff's concept (introduced in 1938) of *Leistungsverwaltung*, reflecting the change from the traditional intervention state (*Eingriffsverwaltung*) to a state administration that provides, in addition, welfare services and infrastructure.

Justifications

All of the Nazi regime's official legal measures – starting from the *Machtergreifung* between January and March 1933 – were justified by legal scholars, in legal philosophy as well as in legal doctrine. Carl Schmitt, for example, justified the Röhm murders in 1934; Karl Larenz and others provided reasons for legal discrimination against Jews. It was no problem to accept eugenics; the presidents of the regional appeal courts and the chief public prosecutors were informed by the ministry of justice about the euthanasia program in April 1941; in turn, they showed no opposition. For the excessive use of the death penalty, one could refer to the saying that hard times require hard measures.

Nazi law – legislation, court decisions, and legal doctrine as well – was full of moral notions. In all legal domains, notions such as honor (*Ehre*), faith (*Treue*), and grace (*Anstand*) were applied. Likewise morally laden were the negative counterparts such as malice (*Heimtücke*), infamy (*Schande*), inferior motives (*niedrige Beweggründe*), and blighter (*Schädling*) (see Gross (2010) for the morality of the Nazis). Hitler stated in 1933, addressing the *Juristentag* (the traditional public meeting of jurists), that law and morality were no longer separated.

Was It Law?

In general, we may doubt – from a legal–philosophical point of view – whether Nazi law was law at all, whether a legal system existed under the Nazis. It is not necessary to rely on natural law in order to deny the term law to what the Nazis called law, as did Gustav Radbruch after 1945 in the case of extreme injustice. From a rather empirical point of view, Ernst Fraenkel (Fraenkel, 1941) called the regime a 'dual state,' combining a 'normative state' and a 'prerogative state.' The normative state – traditional state agencies, in particular the courts – acted 'according to the law' in dealing with nonpolitical issues; while the prerogative state, the 'organs of dictatorship,' acted 'according to given conditions' in what they defined as political matters. While the normative state contributed to the rational calculability required in a capitalist society, the prerogative state aimed at the oppressive creation of the *Volksgemeinschaft*, the dissolution of the institutions of the working class, and the persecution of political foes. Fraenkel finished his manuscript in 1938 before he left Germany. In American exile, Franz Neumann (Neumann, 1942/44) came to the conclusion that Nazi Germany was a 'non-state.' Conflicts between various power groups – parts of the state administration, party cliques, big business interests, the military forces, and the SS–police complex – resulted in a chaos of competences and a polycentric dissolution of legality as the traditional mode of state organization.

In his pragmatic jurisprudence Lon Fuller (Fuller, 1969: p. 39) describes "eight distinct routes to legal disaster": no rules at all but only ad hoc decisions; failure to publicize; retroactive legislation; failure to make rules understandable (e.g., extremely vague rules); contradictory rules; rules that require conduct beyond the powers of the affected party; too frequent changes in the rules; and no congruence between the rules as announced and their actual administration. According to Fuller, the Nazis did not create a bad system of law; instead, their attempts resulted in "something that is not properly called a legal system at all" (Fuller, 1969: p. 33).

Abstract

Fiction, drama, filmmaking, and art play a significant role in the Middle East and North Africa (MENA), where intellectuals are often considered spokespersons for the people to the regime. From Morocco to Iran, they have a moral authority that promises influence, imposes responsibility but also invites manipulation by those in power. This article provides a historical examination of the production of culture from the end of the nineteenth century to the revolutions of the twenty-first century. Language reform, war, Palestine, gender justice, Islam, and decoloniality have figured importantly on the MENA cultural scene. During the past 20 years systematic translation of MENA literature and new film festivals featuring MENA cinema have helped to globalize MENA culture.

Culture in postindependence Middle East and North Africa (MENA) is the ensemble of literary and artistic production that reflects the norms and values of daily life. Fiction, drama, filmmaking, and art play a significant role in the public sphere where intellectuals are often viewed as spokespersons for the people to the regime. They have a moral authority that promises influence, imposes responsibility but also invites manipulation by those in power. This article examines the production of culture from the end of the nineteenth century to the revolutions of the twenty-first century.

The MENA have come to be conjoined as the Arab world, with Turkey, Iran, and, more recently, Israel as non-Arab neighbors. Scholars have traditionally treated the region as a separate and more or less isolated block, yet it never was. Framing the southern and eastern shores of the Mediterranean, this area is geographically, historically, and culturally connected with Europe.

In his influential *Orientalism* (1978), Edward Said argues convincingly that eighteenth- and nineteenth-century military and political incursions from the northern rim were accompanied by an equally violent discursive campaign that created an "ontological and epistemological distinction between the 'Orient' and (most of the time) 'the Occident'. [Orientalism was a] Western style for dominating, restructuring and having authority over the Orient" (Said, 1979: 2, 3). Apparently objective orientalist scholarship in most disciplines in fact served the political ends of their governments and shaped domestic practices and policies. Postcolonial scholars have revealed that European portrayals of MENA as primitive, barbaric but ripe for conversion are colonizing projections. Yet orientalists' representations had the force of truth at the time, and they were remarkably influential. Arab, Turkish, and Iranian intellectuals writing during the nineteenth and early twentieth centuries often built on such positivist foundations. 'Progress' became the leitmotiv of the civilizing discourse and missions. Failure to modernize adequately was predicated on the inability to imitate the West.

Nineteenth-Century Nahda

To understand the role of culture and especially literature in the Middle East we must first glance at its history. Although Middle Eastern literatures have become privileged sites for recording and engaging with sociopolitical tensions and conflicts, this was not always the case. In the medieval and early modern periods, Middle Eastern literatures had been the preserve of the elite, providing them with literary frames in which they might elaborate an already familiar tradition and demonstrate formal skills and erudition. Popular literature such as *A Thousand and One Nights* also relied on the already known. Social commentary was generally downplayed.

The arrival in the late eighteenth and nineteenth centuries of the French and British colonial expeditions, with their technological, cultural, and intellectual institutions, forced a new look at society and culture. Contact with European modernity cast Islamic cultures in a poor contrastive light. Egyptians in particular, because they were the first to experience French colonialism, became concerned to learn about Western culture and science. Under such Ottoman governors as Muhammad Ali Pasha and his son Ibrahim Pasha, groups of male Egyptian scholars traveled to Western Europe, and particularly to France, to study scientific texts and to translate them into Arabic. Because of the enormity of the task, these scientific missions might stay for months on end in Europe where they were introduced to theater and modern literature. The newest and most intriguing genre was the novel, and these men returned with translations of European masterpieces by Honoré de Balzac, Gustave Flaubert, Leo Tolstoy, and Ivan Turgenev, to mention only a few. Some intellectuals came to believe that the writing and function of literature in the Middle East had to change to accommodate their new realities. They also knew that conservatives might resist the introduction of new genres, fearing the great classical literatures of the Arabs, Persians, and Turks might not survive the invasion of the trivia of the modern world. Others saw in the dialogue between their own cultural traditions and those of others the possibility of reimagining national identity within a common modernity.

The Question of Language

Whether they were closed or open to the outside world, Middle Eastern intellectuals considered the question of language to be vital in the process of modernization. Some interrogated the boundary between high-culture languages and the vernaculars,

while others considered the implications of importing foreign words. In Iran, the key was to "disassociate from the Islamic past and to project a 'pure' national origin. … The invention of an idealized past was contemporaneous with the restyling of language, which was achieved in a dialogic relationship with Iran's Arab-, European-, and (the often ignored) Indian-Other. … The Persian language was reconstituted as the essential component of Iranian national identity" (Tavakoli-Targhi, 1990: 77, 86). History could not be reconceived without a radical transformation of the language and its grammar.

The Turkish and Arabic linguistic situations were more extreme than the Iranian because of the distance between the written and spoken languages. Indeed, in both cases there had emerged a kind of bilingualism. The written language of the Turks was so different from the spoken that it was even named differently: it was called Ottoman Turkish. Written in the Arabic script and filled with Persian and Arabic vocabulary, Ottoman Turkish was a distinct language with its own rules of grammar (Halman, 1982: 36). Paradoxically, the poetry of the fourteenth-century mystic Yunus Emre, written before the Ottomans' importation of a foreign lexicon, is more accessible to Turks schooled in the post-Atatürk era than the literature they learned from their grandparents. Mustafa Kemal Atatürk's Westernization campaign, erasing Islamic elements in the language and introducing the Latin alphabet, put an end to the 'bilingual' situation that had pertained in Turkey for centuries. There has been no comparable revolution in the Arab world, and so the split between the classical and the many local colloquial Arabic languages persists. The codification of the spoken language is still tentative because the Arabic of the Qur'an retains its place of honor as the literary medium of expression. Without consensus over the codification of the colloquial, some fear a tower of Babel in which multiple, mutually incomprehensible local literatures would vie for a small spot on the grand stage of what had once been a unified literary tradition. The answer has been to create a modern standard Arabic used by the media and understood from the Atlantic Ocean to the Arabian Gulf.

Anxieties about language were compounded by the imposition of colonial languages. French had become the lingua franca among Middle Eastern intellectuals, even in countries like Turkey that the French had not colonized. French, English, and Russian writers in French translation provided models of how to represent current crises and concerns. Translations of nineteenth-century European literature were followed by literary experimentation.

A New Public Sphere

The literary hub of the Arab Middle East in the early twentieth century was Egypt. Intellectuals censored at home moved to Cairo. Literary salons convened men and sometimes even women to discuss the latest developments in politics and literature. At a time when most middle- and upper-class women were confined to their homes, these gatherings of intellectuals were almost the only places where women could appear with men. Literary schools in Egypt, such as the Diwan School, the New School, and the Apollo School (none of which included women among their numbers), encouraged the production of new kinds of writing that were then often published in their own journals and newspapers. These debates and their publication produced a new public sphere. Discussions about national identity and the new roles women and men were expected to play in the future nation became matters concerning everyone and were no longer restricted to a small community of scholars, often religious scholars. In the process, new conceptions of literary criticism appeared.

The new critics' insistence on the centrality of the imagination in works of art and the need for the work to interact with and hopefully to change society influenced a new generation of critics and writers. The notion that criticism should not be descriptive but rather investigative led to some radical challenges. Taha Husayn (1889–1973), the Egyptian doyen of letters and author of dozens of books, including novels, works of philosophy, and his own autobiography, titled *The Days* (1929), led the charge. New literary critical tools opened up old texts and revolutionized literary production.

Simultaneous with this literary activity in Egypt, two revolutions broke out in Turkey and Iran. Young Turks and Iranians brought up on Enlightenment ideals rebelled against autocratic, self-indulgent rule by the last rulers of the Ottoman and the Qajar Empires. Between 1919 and 1922 Mustafa Kemal (1881–1938, known as Atatürk after 1933) waged war against the British, French, Italians, and Greeks. Expulsion of foreigners was followed by a series of revolutions that continued beyond the 1923 founding of the Turkish republic. After abolishing the Ottoman caliphate in 1924, Atatürk implemented his secularization program and introduced a new Europeanized dress code.

In 1905, Iran was rocked by its constitutional revolution. The period was rich with new kinds of writing. These liberal and often socialist writings depict the turmoil of the period and react against the social irrelevance of the Qajar writers. After his coup in 1921, Mohammad Reza Shah became absolute monarch. He introduced strict censorship and centralized control, but he also concerned himself with the position of women. In 1936, perhaps in response to Atatürk's recent prohibition on the wearing of the veil, the shah enforced unveiling.

Such legislation against veiling should be seen against the background of late nineteenth-century debates about feminism going on throughout the Middle East and beyond. Claims on behalf of women's education were entering the public sphere. Research by feminist scholars both in the Middle East and elsewhere has revealed that it was women themselves who were the first to raise the issue of women's absence in decision-making positions at the national or local levels. Yet it was not until the men took up the 'woman question' that it became a common concern. Atatürk's fascination with the West, where feminists were beginning to attract attention, had predisposed him to advocate women's rights. After coming to power, he gave them the vote.

During the 1930s, some writers began to look for an indigenous, premodern greatness to rival the cultures and power of the Europeans. Marginalizing Islamic influences, intellectuals turned in the 1930s and 1940s to the Pharaonic, Babylonian, Ugaritic, ancient Persian, and pre-Ottoman civilizations. Arab critical schools such as Diwan (1920s) and Apollo (1930s) brought together poets and critics schooled in

England and France who saw the need to knit Western theory into local literary traditions. Discussions about national identity and the new roles women and men should play in the future became matters of general concern.

Independence Struggles

During this same period, the European Zionist movement was becoming active and more Jews emigrated from Europe to settle the land of Palestine. Zionism at that time was primarily a socialist ideology owing more to Russian-inspired communism than to Judaism. As such it looked much like the *missions civilisatrices* that the French and the British had been dispatching to the Middle East since the eighteenth century. In 1948, when most MENA countries had either achieved their independence or were close to it, Palestine was recolonized and transformed into the home of Jews flooding into the region out of fascist Europe.

The region was in turmoil, and MENA intellectuals began to address the effects of rapid change. Saudi exile Abd al-Rahman Munif (1933–2004) situated his five-volume novel *Cities of Salt* (1980s) in a recently oil-rich desert state. As a petroleum economist, he understood the environmental and demographic impact of oil exploitation. The reader witnesses the growing brutalization of the bedouin as they recognize that in this new world of competition and profit, there is more to be gained by individual enterprise and greed than in tribal solidarity. The Iranian writer Al-e Ahmad (1923–69), son of a Muslim Shiite cleric, coined the term 'westoxification' that became a slogan used against the Shah. For him, as for many of his contemporaries, the cultural, economic, and political subordination of MENA countries to the West was anathema. The future had to be modern but not westernized. It was this antioccidentalism that led to the Islamic Revolution of 1978. Scholarship of this period has emphasized growing self-confidence and identification with movements opposed to EuroAmerican neocolonialism.

War Stories

Conflict and violence are so much a part of MENA history and culture that no consideration of its culture can afford to ignore them. The Palestinian struggle against Israeli hegemony since 1948, the Algerian War of Independence (1954–62), the various Arab–Israeli wars but especially the 1967 war, the Lebanese Civil War (1975–92), the Iranian Revolution (1978–79), the Iran–Iraq War (1980–88), the Gulf War (1991), the 2003 US invasion of Iraq, and the 2009–12 uprisings in Iran, Tunisia, Egypt, Libya, Yemen, and Syria are the best known of the MENA conflagrations. Each war produced its own coherent body of literature with women also actively engaged.

After the establishment of the Israeli state in 1948, Palestinians wrestled with their new loss of independence. Although many left, a few, like poet Mahmud Darwish (1942–2008), did stay behind what came to be called the Green Line. Darwish's family had left in the first exodus but soon stole back in. They returned after the period for registering Palestinians had passed, and so the poet's writings dwell on the lack of identity papers. His poem 'Identity Card' (1965) became emblematic of the Palestinian condition. Founder of the binational Israeli Communist Party, Emile Habibi (1921–96) won prizes for his 1974 *The Secret Life of Saeed, the Ill-fated Pessoptimist: A Palestinian Who Became a Citizen of Israel* that tells the picaresque tale of a hapless Palestinian stumbling through life in Israel. Two years later, from Nablus inside the Occupied Territories, Sahar Khalifa (b. 1941) published the first of three novels on the experience of Israeli occupation. Her heroines demonstrate how women's ways of fighting are more effective than those of the men. In the post-1967 period, some Palestinians within Israel wrote in Hebrew. Anton Shammas (b. 1941) wrote *Arabesques*, an autobiographical novel that has been hailed by some as a masterpiece of Hebrew prose. Yet despite the critical acclaim, the novel has not been fully accepted as part of the canon of Hebrew literature. Shammas has described this work as his challenge to the Israeli claim that Palestinians living under Israeli rule could be integrated as Israeli citizens. No matter how assimilated they tried to become in Israeli society, no matter how excellent the Palestinians' command of Hebrew, they could never become Israeli citizens in the full sense of the word. Shammas was long in conversation with A.B. Yehoshua (b. 1936) considered one of Israel's most important fiction writers and social critics. His fiction unveils the Arab in the Jew. In his first novel *The Lover* (1977), he points to the dreaded other that is always there, lying in wait for the opportunity to reveal itself. The figure of the Arab lies at the core of Israeli identity, disturbing the unmarked Europeaness of Israeli identity. The more it is repressed the more violent its ultimate eruption into consciousness. Iraqi Israeli Sasson Somekh (b. 1935) narrates the challenges faced by Jews in Arab countries who lived in the interstices between local and colonial systems that both privileged them as Jews and emphasized their outsider status.

Women's versions of their experiences of national violence have challenged the familiar frame narrative that characterizes men's war stories. They have insisted on the importance of their contributions to the national welfare. In the 1980s, the Algerian novelist and historian Assia Djebar (b. 1938) started to publish her semiautobiographical quartet. Through the eyes of women she radically revises Algerian colonial history, linking her own experience with the stories of neglected nineteenth-century women resisters with those of living women who had been active and then silenced during the war of independence from the French. The 1990s attacks by Islamic fundamentalists on intellectuals, and particularly women, in Algiers perpetuate a war that was not resolved in the early 1960s.

In Lebanon the Beirut Decentrists, a school of women writers, wrote about the civil war. Some analysts have argued that political anarchy relaxed social norms so that the prohibition of women writing about war, an experience they have always been said not to have had, was lifted. Beirut became emblematic of postmodern wars that erase the boundaries between binaries, like home and front, which have been so necessary to the effective telling of the War Story (Cooke, 1997). Critical of participants in the senseless fighting, they also exposed the literary recklessness of those who wanted to represent the war as having any moral sense. Emily Nasrallah (b. 1938) wrote about the devastating effects of the civil war and the massive emigration it precipitated. Hanan al-Shaykh's (b. 1941) *The Story of Zahra* (1980) traces the growth in consciousness of a woman whom the war empowers.

In 1980, while the war in Lebanon was at its height, the Iran–Iraq War broke out. Scholars from the region as well as those from outside have pointed out that Saddam Hussein, like many dictators, has had an ambivalent relationship with the intellectual elite of his country. He needed them and therefore he feared them. Throughout the war, he coerced the writers and artists to glorify the war in ink and paint. The Ministry of Culture established literary series and organized festivals in honor of the war to which scholars of Arabic literature from all over the world were invited. Many Iraqi writers and artists did as they were told. Some did not. Under the very eye of the censor, some writers managed to articulate criticism of a war they were supposed to praise (Cooke, 1997). Not only writers and artists, but literary critics also were commissioned to describe and analyze the cultural effects and products of the war. So prolific were they that by the late 1980s books of criticism about the literary criticism of war literature were being published.

Ironically, the Islamic government of Iran was doing exactly the same as its enemy, namely sponsoring praise of the war and censuring whatever was seen to be oppositional to its Islamic interests. Some writers complied with the government's will; others protested. A. Rahmani's 'Short Hike' acts out a moment of defiance between an Islamic guard and the woman he has reprimanded for revealing a strand of hair. Restrictions forced women to speak out (Milani, 1992). Many fled to London, Paris, Los Angeles, and New York that have become MENA exile capitals. Observing their native lands from a distance, creative artists and critics publish works of political, social, and cultural analysis as well as fiction and memoirs.

In March 2003, a year and a half after the 9/11 attacks on the World Trade Center in New York and the Pentagon in Washington DC, the US military invaded Iraq. The pretext was Iraq's alleged complicity in 9/11 and the goal was to eliminate the weapons of mass destruction that until today have not been found. After toppling Saddam Hussein, the American forces stayed another 8 years. Sectarian violence spun out of control. Young bloggers were the first to inform the world about life in Iraq under American occupation. Two have achieved renown: Salampax and Riverbend. Both of them have published books of their blogs; indeed, this melding of blog and literary text has become a trend in contemporary Arabic literature. In 2007, Sinan Antoon published his *I'jam: An Iraqi Rhapsody*, an imagined prison memoir that recollects the anxiety and fears that ruled Iraqis' lives since the war with Iran. The US military pulled out in 2012 having overseen the destruction of the country.

Writers, filmmakers, and artists, especially grafitti artists, were active in the Arab uprisings of 2010–12. Like the Tunisian muralists, the Egyptian Ganzeer painted his commentary on to Cairo's walls and inspired the young people to continue their stand against the government. Short story writers and filmmakers collaborated to produce films like '18 Days' that within months of the resignation of President Mubarak were making the rounds of international film festivals.

Political Commitment and Prison

Political independence in MENA countries demanded political and moral vision that would owe as little as possible to European norms. Intellectuals set out to 'revolutionize the revolutions'. In 1946, the Iran-Soviet Society sponsored the first congress of Iranian writers, which called for the centrality of ideology to literature. Seven years later in Lebanon, the first editorial of the influential monthly periodical *Al-Adab* declared that all forms of writing must be politically engaged. The time of art for art's sake had passed to be replaced by a revolutionary ethic in all creative activities.

The project of cultural production from inside authoritarian regimes is fraught with danger: just how much criticism is too much, how much too little? Nevertheless, despite the dire consequences for articulating opposition, public intellectuals rarely flinch from what they consider to be their responsibility. Some are killed for their words. Many are imprisoned. So many have published books about their prison experiences that it is possible to talk about a body of MENA prison literature that is beginning to receive the critical attention it deserves. The fact that intellectuals have had such experiences that they then publish them gives them a moral authority others may never achieve.

For many MENA intellectuals prison is a badge of honor, exile a terrible necessity, cooptation an ever-threatening possibility. Public intellectuals in many MENA countries are closely watched. Since books, plays, paintings, and films may assume the force of a political manifesto, governments as well as some nongovernmental associations try to monitor cultural production before, during, and after its completion. Intellectuals judged to be dissident may be eliminated, exiled, or coopted. Cooptation is a widespread phenomenon in MENA, making arduous the decision to stay in one's country. Filmmaking is particularly susceptible. Like theater, film watching is a communal experience and as such it allows individuals to share with an anonymous group a sense of justified anger, or to laugh at the expense of oppressors. The power of such cathartic moments has not been lost on repressive regimes: national film institutes sponsor, censor, and retain monopoly of the finished product. Since the Islamic Revolution, Iranian filmmakers, like the internationally recognized Mohsen Makhmalbaf, have had to submit their scripts, rushes and final films to the government censors, who are especially concerned with Islamizing the representation of women. During the latter part of Hafiz Assad's rule, Syrian filmmakers were sponsored to produce films that were remarkably critical of the regime yet rarely shown. Films like Muhammad Malas' *The Night* (1991) are only shown during international film festivals. People know of their existence and long to watch them. In his *Historical Miniatures* (1993), the Syrian playwright Saadallah Wannus (1941–98) examines the triangular relationship among state, society, and public intellectuals through the controversial meeting of the fourteenth-century Mongol tyrant Tamerlane with the North African historian Ibn Khaldun. Mamduh 'Adwan's (1941–2005) play *The Ghoul* (1996) focuses on the cruelty of the last Ottoman governor sent to Syria. He warns at the end of the play that if the tyrannical system is not crushed it will recur, and it has with the rise of Bashar Asad. The 2011–12 mass revolt of the Syrians against the regime seems to respond to Adwan's call to the people not to cut off the hand of the jailor but to destroy the prison. The viciousness of the government's response to the people's initially peaceful requests for reform has shocked the world.

Exile

For some the cost of staying at home is too much to bear, and so they leave. Citizens of repressive regimes flee so as to find a place where they might breathe and speak freely. They have congregated in major cities like Paris, London, Buenos Aires, New York, and Los Angeles, where they have founded publishing houses and launched newspapers and magazines.

The Palestinian case has become emblematic of the dilemma of many MENA intellectuals: they cannot live at home, they scarcely survive outside. Should the committed intellectual fight or write or do both or neither? In 1963 Ghassan Kanafani (1936–72) published his *Men in the Sun*, which was turned into a film entitled *The Dupes*. This novella explores the possible outcome of the decision to leave one's home and to seek refuge in Arab countries. The fugitives suffer multiple humiliations before they perish on their way to Kuwait.

Those who write in exile often feel farther from home than the miles that mark that distance. Yet in a world whose borders are increasingly porous, where migration is a necessary part of many people's lives, a new kind of cultural nationalism enhanced by social networking is emerging. It allows those who are living far from their land of birth or ancestry to retain very real ties of identity. Turkish novelist Habib Bektas (b. 1951) is a good example. Since 1972 he has been living and writing in Germany. In 1997, his book *The Smell of the Shadow* won the Turkish Inkilab Kitabevi Press annual prize; it was the first time this coveted prize had been awarded to a nonresident Turk. Bektas explained that his Turkishness did not consist in residence in Turkey but in language: he lives in Turkish. This adoption of the language as nation is a strategy many writers in exile invoke.

Islam and Revolution

Religion has come to play an increasing role in MENA societies and culture. The success of the Shiite Islamic Revolution in 1979 Iran marked a radical turning point in regional politics with Muslim ideologues leading the charge. Scholars, especially Western-trained anthropologists, have asserted that the wide distribution of cassette tapes of charismatic preachers' Friday sermons provide even the illiterate with a new vocabulary and syntax. Whether the Islamization of the public sphere is regarded as a good or a bad thing, it has created a new kind of public sociability that entails a mandate for public intellectuals, even the most secular of them, to learn its language. The attack on the Twin Towers in New York City on 9 September 2001 announced to the world the founding of al-Qaeda, an Islamist terrorist organization under the leadership of the Yemeni Saudi Osama Bin Ladin committed to opposing Western capitalism and ungodliness in the world.

Public intellectuals are under constant surveillance by the government and vigilante groups. The case of Salman Rushdie and Ayatollah Khomein's 1989 *fatwa* against him for his 'heretical' *Satanic Verses* (1988) has entered the annals of world history. In the mid-1990s Algeria, the Islamic Salvation Front was voted into office by the people. When the government canceled the election, the Islamists turned their anger on intellectuals. Films have been made on the senseless killings.

Moral censure of literature has escalated to sanction for deadly assaults on the authors. In 1992, Egyptian Islamists assassinated Farag Foda, a journalist, for his critique of their discourse, especially in his *Before the Fall* (1992). That summer, they published in paperback format the proceedings of a trial of the Egyptian writer, physician, and activist Nawal El Saadawi (b. 1931) they had conducted, titled *Nawal El Saadawi in the Witness Stand*. With its cover picture of a wild, white-haired woman staring out from behind bars, the book was so widely distributed that it could be found on the blankets of Cairo sidewalk book vendors, selling for a few piasters. She had called for the 'Lifting of the Veil from the Mind' in her Arab Women's Solidarity Association (founded 1982), in her lectures given all over the world, and in novels like *The Fall of the Imam* (1987). For that they condemned her to death.

Feminists from within the region are analyzing the situation, forming contingent coalitions, and proposing new ways to challenge the policing of women's actions, behavior, and speech. They have recognized the dangers inherent in Islamists' declarations that women are the symbolic and moral center of their society. What they do and how they act have become men's affairs. It is within this context that the veil, abandoned or even banned in most places during the first half of the twentieth century, has reassumed such central importance. In places like Afghanistan, Iran, Algeria, and Sudan, the unveiled woman may be reflexively labeled wanton. Although the veil is not Islamic, it is seen by many to be highly recommended. There are several problems with this highlighting of the veil as an emblem of the society's moral rectitude. Feminists in the late nineteenth and early twentieth century fought against the veil as a symbol of men's ownership of women. To go back to wearing this patriarchally loaded symbol is to renounce the gains of their grandmothers. Another problem with the blanket mandate that women veil is that not all women in MENA countries are Muslims. At the other end of the political spectrum are Islamist women like Zaynab al-Ghazali (b. 1912) whose prison memoirs, *Days from My Life* (1977), enact a model of women's empowerment within orthodox Islam (see Cooke, 2000).

Translation and Recognition

MENA literature, art, and films are now enjoying international recognition, as they enter the mainstream of world culture. Three writers have won the Nobel Prize in literature: the Israeli Shmuel Yosef Agnon (1888–1970) in 1966; the Egyptian Naguib Mahfouz 1988; the Turkish Orhan Pamuk in 2006. In 1989, the Moroccan Tahar Benjelloun won the Prix Goncourt, the first Arab to be awarded this coveted French prize. In 1997, the Turk Yashar Kemal was awarded Italy's most prestigious prize, the Nonino Literary Award. In that same year four Iranian films were awarded major prizes at Cannes, Locarno, Tokyo, and Montreal. Many countries host annual film festivals with latest additions being Dubai, Abu Dhabi, and Qatar.

Arabic, Hebrew, Persian, and Turkish fiction and poetry are being translated into European languages. In 1981, the Palestinian poet and literary critic Salma al-Khadra' al-Jayyusi founded her Project for Translation from Arabic in the United States. Whereas the first translations found homes in marginal presses dedicated to publishing works by writers from the

global South, by the late 1980s major European, American, and even Japanese publishing houses started to adopt literary series as well as individual authors. The growth of the translation industry is significant for readers, who now have unprecedented access to the cultural imaginary of people they had previously known through the stories of scholars and travelers only. It is important above all for the intellectuals who are writing with the awareness that their works will be translated, that what they say about their culture is being consumed far from the local readership they had originally targeted. Writing thus entails consequences that must be anticipated. MENA intellectuals are seeing their books and films becoming part of a global cultural project in which they should play an increasingly visible role.

Abstract

The question of women in the Middle East is not a secondary but an agenda-setting issue for the broader historical, political, and cultural processes that have shaped these societies. Women's status and agency were central in the shaping of movements of modernization, state-building processes, nationalist ideology, and Islamist protest movements. Women's visibility and participation in public life and emerging gender consciousness can be distinguished as a motor of change, having an impact on not only the lives of women, changing male–female subjectivities, but also on the course of Middle Eastern history. In a similar way that modernist experience is transmitted by unveiled bodies and secularized ways of life, Islamist identity and difference are embodied in women's veiling and disciplining the religious self. Women's position and agency in society are decisive in shaping the interplay between Islam and modernity: new definitions of self, modern, and Muslim are emerging from this conflictual but creative encounter. Understanding the distinct trajectories and identity formations that Muslim women follow, thereby changing the interpretations and interactions between religion, traditions, and modernity can provide us with new intellectual tools for a critical reflection on the general field of gender studies.

Introduction

The study of women and gender has opened up a new perspective in our approaches to Middle Eastern history and society, in particular interactions between women's issues and such major cultural and political movements as national independence, social reform, and modernization movements in the nineteenth century and Islamist movements revived by the advent of Islamic Revolution in Iran in 1979. It observes changing approaches to the study of women and history in the Middle East, and their implications on gender studies in general.

'Gender' studies began to appear in the 1980s, first in the United States and soon afterward in Europe and parts of the Middle East, in the wake of the new discipline of women's studies, which was itself an academic and intellectual outcome of the feminist movements of the 1960s and 1970s. It was a new attempt to reveal unspoken inequalities and power relations between men and women. In contrast to the biological differences highlighted by reference to 'sexes,' the term 'gender' depicts socially constructed, culturally specific forms of masculinity and femininity that are subject to social interpretation, negotiation, and change. Furthermore, gender is used, not exclusively in relation to women's issues, but as a constitutive element of all aspects of human society and organizations, such as the family, economy, science, medicine, state, and politics. The analysis of the ways in which different aspects of social life, history, and culture are gendered, namely embedded by culturally perceived differences within a field of power relations, has become a major concern for social sciences. Few concepts have transcended cultural and geographical boundaries so powerfully during the 1980s and 1990s as gender. This has contributed to pioneering work on gender within the field of Middle Eastern history (Keddie and Baron, 1991). Gender awareness has changed ways of studying the history of colonization, state building, nationalism, and Islamic identity in the Middle East. At the same time, tracking the distinct trajectories and identity formations followed by Middle Eastern women, both Muslim and non-Muslim, renders a new map for critical reflection in gender studies. As concepts travel in two directions, they create new avenues of learning, dialogue, and interaction between the West and other cultures, ranging from academy and law to citizenship. This new dialogical concern revitalizes an interest in the study of local cultures and in cross-cultural comparative perspectives.

For at least a century, the problematic link between modernization and cultural identity in the Middle East put women at the heart of political and societal debates. Discussions on the appropriate position for women in Muslim countries continue to underpin any political discourse aiming at the reorganization of these societies. Women are situated at the crossroads between two distinct sets of values and affinities, namely between universalism, secularism, and feminism on the one hand, and cultural authenticity, religion, and Islam on the other. Or, to put it succinctly, in Middle Eastern societies, gender issues are embedded in civilizational issues in the sense that women's position in society is the determining factor both in framing and intertwining what were posited as the existing dualities, such as traditional/modern, religion/secularism, Islam/the West, equality/difference, and interior/exterior. Studies on women in the Middle East not only follow common and overlapping trends with Western feminist thought but also reflect the distinctive centrality of gender issues in Middle Eastern societies.

Women's Civilizing Mission

The social position of women began to be discussed with the onset of modernization attempts in the nineteenth century. As modernization seemed to imply Westernization, the ultimate question that reformists needed to answer was whether Islam was compatible with Western civilization and more particularly with women's rights and freedom. Different answers to that question – ranging from national modernists and Islamist

reformists to religious conservatives – continue to put their stamp on the intellectual and political history of the Middle East. Analysis of these historical debates from the point of view of women's questions has shown discursive parallels in countries such as Egypt, Turkey, and Iran (Ahmed, 1992; Badran, 1995; Gole, 1996; Najmabadi in Kandiyoti, 1991). For progressive nationalists, the emancipation of women from 'erroneous' religious prescriptions and traditional ways of life was the prerequisite for national progress. Islamist reformists asserted that Islam was not a barrier to progress and that it was possible in Islam to embrace modern ideals, such as gender equality and human rights. But for conservatives, any change in the direction of Western modernity, especially pertaining to women's position in society, would have meant a loss in cultural identity and consequently, to preserve moral integrity and social cohesion, gender relationships were to be framed according to the Islamic religious law (*Shari'a*) as they understood it.

As markers of cultural identity, women, therefore, set the agenda for different and competing social projects. Furthermore, the most disputed issues throughout the nineteenth and twentieth centuries, namely polygamy, veiling, gender segregation, women's education, employment, and participation in public life, remained on the public agenda of Middle Eastern countries in the 1980s and 1990s.

The Middle Eastern model of early modernization, namely the era of colonial, postcolonial, and nationalist state building, can best be summarized by a formula that equates women's emancipation and national progress. With striking similarities between Turkey, Iran, and Egypt, and also with the North African countries, women's public visibility and gender equality are considered to be the yardsticks of progress and civility. Turkish Kemalist nationalism articulated and implemented gender equality as an intrinsic part of its modern identity and societal reforms. Women gained full political rights in 1934, and the removal of family law from the jurisdiction of religion with the enactment in 1926 of a secular Civil Code (adapted from Swiss law) in Turkey can be considered as the most radical example of engagement in secular feminism. In Iran, too, women's rights, free education, and compulsory unveiling in 1936 were implemented by the secular nationalist politics of Reza Shah. In Egypt, alongside nationalism, the Islamic reformist movement (especially in the works of Muhammed Abduh and Qasim Amin) paved the way for women to gain access to public life, to claim a public voice, and to demand educational, work, and political rights. Veiling was criticized as a sign of women's confinement and as an obstacle to women's participation in public life. Thus, the removal of the veil and the head covering of women in public became a symbol of women's emancipation as well as national progress. A well-known Egyptian feminist, Huda Sharawi, announced the start of the feminist movement when, returning from an international feminist meeting in Rome in 1923, she disembarked from her train in Cairo and unveiled her face in public. Therefore, public visibility of women was put forward by the first wave of feminist activism and writing in the Middle East. A pre-Islamic past, whether Anatolian, Zoroastrian, Pharaonic, or Berber, was idealized as egalitarian in gender relations and celebrated in the construction of a new nationalist idiom. Women, especially upper and middle class women, mostly coming from a traditional universe but exposed to modern ideals and education, were called to participate in this nation-building process, as citizens, educators, and role models for a 'new life' in the family as well as in the public sphere. The limits of women's participation in public life and social agency were framed within the terms set by the nationalist movements whether backed up by secular or religious reformist discourse. Feminist scholarship in the Middle East revealed these issues pertaining to gender and nationalism and developed in distancing itself from and in criticism of nationalist idiom (Kandiyoti, 1991; Moghadam, 1994).

Women and Islamist Movements

The revival of Islamist movements marks the second turning point in contemporary Middle Eastern history where women's issues and agencies once again play a central role, but this time as markers of Islamic differences rather than as transmitters of Western-centered modernity.

Although Islamic movements are far from being monolithic, one can still discern common features in the contemporary Islamist movements that have developed since the end of the 1970s in almost all Muslim countries. Their aim is to transform the whole of society along Islamic lines, ranging from government, law, and science to ways of life, gender relations, and faith. The Iranian Islamic revolution in 1979 provided the political source of reference and legitimacy for such an ideal. Actors of Islam, men and women alike, come mostly from provincial towns and lower social classes, but are an outcome of urban migration and modern education. The pressures generated by the encounter with a modern universe create a need to reinterpret religion and re-adapt gender roles and divisions. A call for a return to the original, unadulterated, fundamental sources of Islam (the Qur'an and the Sayings of the Prophet) has engendered the revival of debates on Islamic knowledge. The interpretation of religious precepts and texts is opened up to public debate in which not only the religious specialists (*ulema*), but also new Islamist figures, both men and women, participate. In a paradoxical way, contemporary Islamism has instigated the democratization of religious knowledge whereby various actors of Islamism can lay a claim on the interpretation of religion and Islamic jurisprudence. Issues related to the segregation of, and discrimination against, women, such as compulsory veiling (*hijab*); religious marriages and polygamy; women's obedience and legal subordination to the husband's authority; inequalities in divorce, custody, or inheritance; and interdictions put on Muslim women's access to religious positions, praying in mosques, marriage to non-Muslim men are no longer issues settled under the monopoly of religious *ulema* but are the subjects of public controversy. Fatima Mernissi has made a pioneering contribution to understanding the specificities of Islamic constructions of female sexuality and spatial social organization, and giving voice to religious women figures in public life and history (Mernissi, 1975). Other academic work followed and contributed to new readings of women's position in religious and legal texts (Stowasser, 1994; Yamani, 1996; Mayer, 1999).

In its criticism of essentialism and reflections on the constructed nature of identity and difference politics, feminist

theory has contributed to the development of new approaches to Islamic identity. Islamist identity is distinct from Muslim identity to the extent that it expresses a refutation of given definitions, accepted ways of 'being a Muslim,' 'born being Muslim' categories, handed down from generation to generation, and asserts a collective and countercultural attitude. Islamism expresses the problematization of Muslim identity both by a return to the origins of religion and by a non-assimilative attitude toward Western modernity. Islamism shares a similar pattern of collective and personal empowerment with other contemporary social movements in the West, namely that of appropriation of their difference (Muslim, woman, or black), the very difference which accounted for their exclusion and stigmatization. Islamism is a collective manifestation of an exacerbated form of Muslim difference. A search for an alternative in Islam endows especially newly urbanized and educated Muslim actors with a very strong quest for an authentic indigenous identity. The covering of women, the 'veiling,' is the most visible symbol of this claim for Islamic authenticity and difference.

In all Muslim societies, the Islamist movements gained public visibility through the veiling of women. On the one hand, the veil recalls the traditional definitions of Muslim womanhood based on values of modesty and virtue, the segregation of sexes, and the interdictions put on women with respect to their participation in social and public life. But, on the other hand, the new veiling signifies the political participation and the active voluntary reappropriation of Islam identity. As such, the new veiling does not represent the traditional images of Muslim women: uneducated, docile, passive, and devoted to family life. On the contrary, young, urban, educated groups of Muslim girls are politically demanding and publicly visible. The way they readopt the Islamic outfit is different also from its traditional outlook.

Traditional Islamic ways of covering change from one region to another, manifesting diverse forms in different national settings (the Iranian *chador*; the 'kerchief' covering the lower part of the face in North Africa; the face mask of the Gulf region; and the Afghan *burqa*). In contrast, contemporary Islamic dress is a new style, almost like a uniform, independent of the national context. Although there is a wide range of styles in Islamic dress, it can be distinguished by a headscarf totally covering the hair and falling to the shoulders, combined with a sort of long and ample overcoat (made of pale-colored industrial fabric) to hide the forms of the body. Overall, the Islamic outfit is a modern reappropriation and reinterpretation of Islamic modesty; the silhouette of women with widened shoulders, carrying big bags, walking in the streets, taking buses, going to the universities, hints at the emergence of a new profile of Muslim women: that of urban, combative women pursuing a career and mixing with men. In short, women are actors of Islamist movements, but they are also following a multifold life and professional strategies, and making part of a modern universe. And this, of course, cannot avoid creating a tension between Islamic precepts, which define the 'ideal Muslim woman' as a homemaking, self-sacrificing mother and wife, and the new individual and professional aspirations of these women. Acquired public visibility, social mixing with men, and intellectual and professional aspirations force them into a tension between their collective role as agents of Islam, as markers of 'authentic Islamic identity,' and their emerging individualist and feminist consciousness (Gole, 1996). Paradoxical it may appear, in promoting the veil as the symbol of their cultural difference, but Islamic movements unintentionally encourage women's participation and visibility in public life, which, in turn, constitutes a subversive potential for gender consciousness and activism.

Women voice publicly their demands for access to education, employment, and political life (Adelkhah, 1991). In the post-Khomeini Iran, women's periodicals proliferate in which women defend gender equality in their readings of religious texts and criticize Islamic jurisprudence. They argue for women's rights such as their eligibility to engage in religious studies, to hold juridical positions, to participate in the lawmaking process, to stand for public office, to have custody of children after divorce, to have equal consideration with men in testimony. In these periodicals, Iranian women argue for a women's rights perspective in their critical readings and interpretations of Islamic law and power.

In Egypt, where there has been a rich tradition of modernist Islamic thought, there is an increasing concern for the feminist consciousness to be religiously rooted in Islam. Whereas in Turkey, where secularism and Islam were radically separated, Islamic women's claim to have the right both to wear the headscarf and to enter into secular public spaces (to attend the universities, to be admitted to public service, and to be elected to the Parliament) addresses not only such questions with new urgency to Islam, but also foremost to secular definitions of feminism and politics. The homogeneous and secular constitution of the public sphere is thus challenged by the emerging claims of religion and difference.

Gender and Multiple Modernities

The entrance of the newly veiled women into the public sphere across the Middle East by political, educational, and professional means stands in continuity with the process begun by the upper and middle class women who took off the veil almost a century ago. Both are products and agents of social change, transforming the relations between tradition and modernity, and religion and secularism. If the first generation of women acted for accommodation and aspiration to modernity, framed by nationalism, the second generation searches resources in religion to act upon modernity. Islamism is yet another moment in the indigenization of modernity in the Middle East; it represents a critical reflexive mode of the appropriation of modernity.

Religious and cultural traditions, rather than being immutable, static, and marginalized, emerge as a vibrant force in the processing of modernity (Fernea, 1994; Gocek and Balaghi, 1994). Traditions are selectively reappropriated and transformed in the light of modern dilemmas that women face at the forefront. Women's employment, political engagement, and public presence, have an impact on the necessity to reconsider the family sphere, the place of motherhood in society, and the values of modesty and primacy of community. Rather than assimilating to the liberal values of modernity and encouraging every move from the private to the public in the name of liberation Islamic politics advances cultural difference

as a form of resistance and as a way to articulate an alternative project. Women's bodies are sites where this politics of difference is inscribed; the new veiling displays the embodied difference. In a similar way that the modernist experience was carried out on unveiled bodies and secularized ways of life, the Islamist difference is crystallized through women. New Muslim subjectivities are worked out by politics of difference, celebrating and disciplining religious self and bodily practices in a modern universe. Muslim women are situated at the crossroads between assimilating modernity and subjugating traditions; gender consciousness provides women with a critical reflexivity, a compass to map out a new trajectory. The interplay between Islam and modernity blurs the distinctions between secular and religious, private and public. New definitions of self, modern, and Muslim are emerging from this conflictual but creative encounter. Women's agency is decisive in determining the course of this ongoing, dynamic process.

The new combinations and crossbreeding between cultural difference and modernity, Islam and gender equality necessitate a new perspective for understanding simultaneous but different experiences of modernity. Approaches in terms of insufficient and delayed modernity do not account for the centrality of women in the Middle East. Studying gender in the Middle East inevitably reinforces local and a cross-cultural comparative perspective.

Abstract

This article reviews the development of Middle East politics as a field of study. It identifies prominent themes and questions that have shaped research on Middle East politics in the United States, Europe, and the Middle East, focusing on comparative politics and comparative political economy. The article emphasizes how the relationship between the study of Middle East politics and the social sciences has changed over time. It concludes with a brief speculation about where this relationship is headed at the turn of the twenty-first century. It concludes with a brief overview of the Arab Spring events that shocked the politics of this region.

The study of Middle East politics has deep historical roots in the social sciences. The Middle East – defined here to include the region that stretches from Morocco in the west to Afghanistan in the east, and from Turkey in the north to the Arab Peninsula in the south – has figured prominently in a tradition of political and sociological-comparative research stretching from Max Weber to Karl Wittfogel and Immanuel Wallerstein. Broadly defined, this tradition has sought to understand why capitalism and democracy emerged first in the West, and how the initial appearance of these forms of economic and political organization in the West affected the developments of non-Western parts of the world. For well over a century, social scientists have drawn, in particular, on the experience of the Ottoman Empire to study political institutions, social structures, and economic arrangements perceived as explicit counterpoints to those that sparked the rise of capitalism and the transition from absolutist to republican systems of rule in the West (Anderson, 1979).

This tradition, in which the experiences of the Ottoman Empire and the Arab states that formed in its wake are used as counterpoints to European experiences – often negative counterpoints – has had a lasting impact on the study of Middle East politics. It established a focus on absolutism, 'predatory rule,' despotism, and authoritarianism as central themes in social science research on the Middle East. The legacy of this tradition has been decidedly mixed. On the one hand, authoritarianism and personalistic modes of governance remain prominent issues in the study of Middle East politics today – appropriately so, given political conditions in the region (Heydemann, 1999; Weeden, 1999). Less positively, this legacy is expressed through research in which individual behavior and collective outcomes are understood in terms of deeply embedded cultural constraints – an essentially authoritarian political culture, for example – that reinforce patrimonialism, undermine prospects for democracy, and impede the development of institutions capable of securing economic growth. Such culturalist assumptions reinforce the impression of Arab (or Muslim) politics as exceptional. They diminish possibilities for integrating Middle Eastern cases into broader comparative frameworks or applying to social and political processes in the Middle East theories and methods that have been used productively in other settings. In practice, moreover, culturalist research has rarely escaped the tautological quality of many theories that rely on culture as an explanatory variable. Largely for this reason, culturalist arguments are less prominent in the study of Middle East politics today than they were in the 1960s and 1970s.

The Post-World War II Period

After World War II, with the rise of the USA as a superpower, and the not unrelated emergence of comparative politics as an established subfield of political science in the USA, the study of Middle East politics made significant contributions to a number of important research programs in the social sciences. These included theories of political development, political decay, and praetorianism (military rule), as well as theories of dependent and peripheral development (Keyder, 1987; Abdel-Malek, 1968). As early as 1956, for example, economic historian Charles Issawi studied the relationship between economic development and democracy in the Middle East, predating the more general work on this topic by Seymour Martin Lipset (1960). Daniel Lerner's *The Passing of Traditional Society: Modernizing the Middle East* (1958) also influenced the subsequent development of modernization theory. His study was cited by Lipset and was noted, as well, in Almond and Coleman's *The Politics of the Developing Areas* (1960), a volume that exerted considerable influence in the USA on the study of politics in the developing world for much of the 1960s and 1970s, both as a model to be followed and as the object of criticism. Samir Amin's *Accumulation on a World Scale: A Critique of the Theory of Underdevelopment* (1974) was an influential contribution to debates about the role of the industrialized North in imposing conditions of underdevelopment on the postcolonial states of the South. Edward Said's *Orientalism* (1978) originated outside the social sciences, but has had a profound and widespread impact on the study of Middle Eastern politics and is central to the rise of postmodernism within the social sciences more generally. Said's work, along with the writings of postmodern theorists such as Michel Foucault, has generated significant interest in discursive and

interpretive methods in the study of Middle East politics (Mitchell, 1988), and revitalized research on power and authority in relations between the Middle East and the West. Other important areas of research in which the Middle East has figured prominently include the study of nationalism, state formation, and state–society relations in the developing world, religion and politics, and social revolution – themes that continue to inform research on Middle East politics today.

For much of the post-War period, therefore, the study of Middle East politics, especially in the USA, developed in a close and interactive relationship with the field of comparative politics and with other disciplines in the social sciences and humanities. During these years scholars of Middle East politics, like their colleagues who worked on other regions, made considerable progress in exploring such concerns as the experience of colonialism and how it influenced the trajectory of political and social life after independence, state formation, the construction of national societies, and the formation of national markets; the political economy of industrialization in the Middle East and the region's incorporation into a global capitalist system; the role of new military elites and the rise of single-party authoritarian regimes; the incorporation of workers and peasants into the political arena and its effects on coalition building and regime formation; the rise of import substitution industrialization as the dominant economic development strategy in the region and the growing role of the state in the economy, as well as the relationship between private sectors and regimes that often pursued, and coercively implemented, highly redistributive social policies; the effects of regime type on a wide range of economic, social, and political processes; the rise of state-corporatist models of interest representation; and more recently the revitalization of 'civil' societies as sites of political contestation.

While these issues were prominent in social science research on Middle East politics within the USA and provided the empirical foundations for theoretical developments in the field, research programs in Europe followed a somewhat different trajectory, less with respect to themes and issues – European scholars, like their colleagues in the USA, engaged issues concerning the state, modes of governance and power, the politics of economic development, and processes of social formation – than to methods and conceptual approaches. Disciplinary boundaries loomed less large among European scholars of Middle East politics, who preserved closer links between history and political science, than became the case in the USA, especially from the 1980s onward. It is also the case, however, that European traditions of linguistic–philological and Orientalist scholarship, as well as the legacy of having ruled the Middle East as colonial powers, were more evident in the concerns of European research programs than in those that developed within the USA. In addition, during the post-War period, the work of European scholars reflected a more assertive engagement with various strands of Marxist political theory than was evident in the Cold War atmosphere of the USA. This was manifest most productively in the development of a rich tradition of labor studies among European, especially French, scholars of Middle East politics. More recently, the presence of growing Middle Eastern communities within Europe has sparked considerable interest in issues such as the dynamics of migration from Muslim societies to Europe, the experience of immigrant life among Muslims in Europe, the politics and political economy of a greater Mediterranean region that links, in particular, North Africa and southern Europe, as well as the impact of expanding Muslim populations on social relations and political processes in largely Christian European states.

Within the Middle East, as well, research trends were and remain heavily influenced by the experience of colonialism. Higher education systems tend to be organized along lines similar to those found in the country that exercised colonial authority in a given place, with scholars in North Africa and Lebanon socialized into French modes of training and scholarship – as well as French academic networks – while training, research, and professional socialization of scholars in Egypt and Jordan reflects (though to a more modest degree) the influence of British rule. However, the most powerful influence on the study of contemporary Middle Eastern politics by scholars working in the Middle East is the repressive political environment found in most Arab states, and the resulting lack of financial support, data resources, and independent institutions capable of functioning as sponsors and promoters of social science research. The research environment in the region varies, however, and scholars in the Arab world continue to work, against the odds, to produce high-quality social science. In recent years, active and vibrant research communities in Morocco, Turkey, Egypt, and Lebanon (among others) have established significant research programs on democratization, Islam and politics, civil society and the role of new social movements, the politics of economic liberalization, as well as regional and international relations. The state of social science research on Middle East politics in Israel reflects the influence on Israeli scholars of trends in American social science, including an emphasis on quantitative and formal methods. Work on Middle East politics also benefits from a more open research environment than elsewhere in the region. However, Israeli research programs also reflect the effects of the protracted and persistent Arab–Israeli and Palestinian–Israeli conflicts, both as a filter that shapes the perspectives of researchers and as a focal point of research programs themselves.

Politics and Society

Since the early 1990s, and still in keeping with broader trends in the social sciences, scholars of Middle Eastern politics have focused attention on issues of gender, economic and political informality, local-level politics, identity politics, civil society, and the dynamics of social movements (Singerman, 1995; Norton, 1996). They have sought to integrate the experience of the Middle East into larger debates in the social sciences around such questions as authoritarianism and democratization (al-Naqib, 1991; Salame, 1994) and the comparative political economy of development (Waterbury, 1993; Waldner, 1999). Inevitably, however, the study of Middle East politics has also emphasized that which is distinctive about the region. Three aspects of Middle East politics have received particular attention from researchers over the past two decades.

First, the relationship between Islam and politics, and the dynamics of politics in Muslim societies more generally have been and remain subjects of considerable interest (Eickelman

and Piscatori, 1996). These became especially prominent in the wake of the Iranian Revolution of 1979 and the increasing visibility of militant Islamist movements and organized Islamist political parties from Morocco to Afghanistan. Second, the social, economic, and political consequences of the oil boom of the 1970s on Middle Eastern states and societies have also sparked a considerable body of research in Middle East comparative politics and comparative political economy that focuses on the fiscal sociology of the state. Perhaps the most enduring contribution of this research can be found in theories of the rentier or distributive state (Luciani and Beblawi, 1987; Chaudhry, 1997) that explore the political, institutional, and social implications of circumstances in which states and governments generate a significant share of their revenue from the sale of natural resources and are not dependent on the direct taxation of their citizens. Whether representative forms of governance can emerge where taxation (the direct extraction of resources from citizens) is low remains a matter of considerable interest in the study of Middle East politics. With the decline of oil prices in the 1980s and 1990s, the question of whether, and under what conditions, states that have not historically developed the capacity to tax might do so has also received some attention.

Third, and not entirely unrelated to work on the political economy of oil, researchers in a number of disciplines and fields, writing from a variety of (often contending) perspectives, have developed research programs focused on the state in the Middle East. Again, this work has been situated largely within political science, and in the subfields of comparative politics and international relations, but has been a core concern of scholars in the Middle East and in Europe as well as in the USA. Here too, moreover, the state as a conceptual category has been approached from a wide range of perspectives, including many that have subjected the category to sustained critical scrutiny. Within comparative politics, one persistent debate has addressed the question of the exceptionalism of the Arab state; whether culture and history (the absence of an experience comparable to the Enlightenment, and the resulting lack of differentiation between religion and state are most often cited in this regard) combined to produce a distinctive form of state, one that defies ready comparison with states in other regions and, moreover, requires distinctive conceptual tools and a special analytic vocabulary if we are to make sense of it. Increasingly, however, researchers tend to operate on the contrary assumption and view the Arab state as simply one variant among a range of state forms. States in the Middle East are shaped by and subject to the same social, economic, and political processes that affect states everywhere, and there is a recognition that these processes are filtered through and experienced within particular historical contexts, institutional legacies, and cultural frames of reference that give state formation in the Middle East a distinctive quality (Zubaida, 1989; Ayubi, 1995). This starting point permits the development of research programs that draw on and contribute to general theoretical frameworks while accounting for both intra- and interregional variations.

In addition, questions about and critiques of the state in the Middle East have also served as the basis for a number of productive research programs. A concern with the fixity or fluidity of state borders in the case of Israel and Palestine served as the basis for Lustick's general theory of how state boundaries change (1993). Mitchell (1991) has used Middle Eastern cases to explore how the impression of a boundary separating the state and society operates to construct stateness as a general attribute, and how this attribute is mirrored in (and, in his view, distorts) research on the state in political science. Migdal (1987) also drew on a nuanced understanding of the state in the developing world, including the Middle East, to explore how societies maintain a measure of autonomous power in the face of states that seem to possess an extraordinary capacity to intervene in and shape societies.

International Relations

In international relations, the contingent quality of state sovereignty in the Middle East and the impact on state consolidation of regimes that were at times highly responsive to transnational, pan-Arab ideologies pose important challenges to neorealist theories of the international system. Pointing to the fluid, fragmented, and contested quality of stateness in the Middle East, scholars of international relations, both those more sympathetic and those more critical of neorealism, have used Middle Eastern cases to question the neorealist assumption that states are like units that operate as unified actors intent on maximizing their security in an anarchic international system. They have worked to develop theories of interstate behavior that account for variability in the nature of state interests and extend more weight to economic considerations, and to the role of norms, ideas, and institutions as determinants of policy making (Barnett, 1998; Mufti, 1996).

At the beginning of the twenty-first century, however, the study of Middle East politics stands in uneasy relationship to the social sciences. Within political science, sociology, and certain subfields of economics, significant research programs have emerged to explore processes of democratization, the transition from state- to market-based modes of economic governance, and the deepening of economic globalization. Yet, as noted earlier, the Middle East remains largely authoritarian, despite limited political openings in some states. The transition to markets has been partial and slow. Linkages between domestic and global markets vary considerably but typically are weak. Economic performance also varies widely, and though trends in the 1990s were positive, overall performance levels remain low. The effect of these conditions has been to limit opportunities for integrating Middle East cases into some current research agendas, notably but not exclusively in the subfield of comparative politics. In contrast to general trends in the discipline, therefore, the study of Middle East politics at the dawn of the twenty-first century has tended to focus less on democratization and democracy than on understanding how persistent authoritarian regimes adapt to changing domestic and international conditions, less on the transition to and consolidation of markets than on the limits of economic reform, less on the impact of global economic integration than on barriers to globalization, and less on developmental success than on persistent obstacles to development. Work on these questions has been profoundly important in explaining political outcomes in the Middle East and holds out significant theoretical value for the disciplines. Yet, they are, nonetheless,

reflective of how the everyday-lived experience of politics in the Middle East has moved the study of politics along paths that differ from those that are grounded in the experiences of other regions in the developing world.

Methodological issues have also constrained the inclusion of Middle East cases into broader research agendas. Generally, the study of Middle East politics rests on the use of case-specific, macrohistorical methods rather than the formal or quantitative methods that are now more broadly applied to the study of politics in other regions. The reasons for this are several, but the methodological orientation of research on Middle East politics results, in no small measure, from the lack of data resources that are needed to undertake quantitative research and a research climate that is not conducive to data collection and dissemination. Thus, while the continuing development of various institutionalist approaches holds out considerable potential for linking region and discipline, and for cross-regional comparative research that incorporates Middle East cases, prospects for building robust research programs that make use of quantitative and formal methods for the study of Middle East politics are limited, at least at present.

Despite these concerns, current tensions in the relationship between the study of Middle East politics and the social science disciplines should not be overstated. Certainly, it should not be permitted to overshadow the presence of a large number of creative, analytically focused, and highly productive research programs both inside and outside the USA. As noted, researchers on Middle Eastern politics have made good use of and contributed to the development of new institutionalist methods. Comparative macrohistorical research coexists comfortably with case-specific but theoretically generalizable research programs that apply a wide range of methods – from archival, discursive, and interpretive to public opinion polling; from network and social movement theories to moral economy and rational choice – all of which are being used to ask important questions about contemporary political life in the Middle East and to engage the analytic concerns of the disciplines. Through attention to the dynamics of political institutions and institutional change; the organization and dynamics of local-level politics and social networks; business–state relations; the relationship between gender, power, and politics; the impact of new information technologies on political life; the formation and transformation of identities; new approaches to the study of culture and politics, and to the role of norms and ideas in political behavior – a list that is far from complete or comprehensive – scholars of Middle Eastern politics are pursuing research programs that not only resonate across regional boundaries but express increasingly sophisticated theoretical perspectives. On this basis, there is reason for optimism that the relationship between the study of Middle Eastern politics and the social sciences is now (again) becoming interactive, reciprocal, and mutually constructive.

A Postscript: Arab Spring

On 17 December 2010, Mohamed Bouazizi committed an act of self-immolation in Tunisia, which led to a series of protests that eventually unleashed widespread political conflict and change throughout the region, an event broadly called 'Arab Spring.' Some countries were affected only mildly. Saudi Arabia faced only moderate protests, while larger protests forced Jordan's King Abdullah to dismiss the government – not for the last time, as the king would have to dismiss several more governments in the face of mobilized public pressure. The Arab Spring had a more fundamental impact elsewhere, perhaps the most dramatic being the overthrow of Muammar Gaddafi's long-lived regime in Libya and Gaddafi's eventual death in the civil war that erupted there. Ultimately, all countries of this region witnessed some degree of political contention, and in four countries leaders and regimes were brought down (Egypt, Libya, Tunisia, and Yemen). Strikes and organized demonstrations have been one fairly common trait of this wave of political change, and social media have been particularly prominent as tools for mobilization and strategic organization.

Much like the collapse of state socialist regimes in East Europe in 1989, which also had a wavelike quality and appeared quite suddenly, Arab Spring was grounded in a combination of deeper institutional causes and proximal conditions. One quality shared by countries in this region was long-simmering public dissatisfaction with leading politicians and parties. Corruption, repressive politics, and other forms of injustice had marked political systems that had various authoritarian traits (with some, such as Libya, relatively more populist than others but still authoritarian). Further, the 2008 global economic crisis had also affected markets and employment in the region, leaving many average civilians unemployed or not well-off economically. These political and economic strains were exacerbated by inability of these authoritarian regimes to address social pressures, either through sufficiently robust welfare measures or through the kind of democratic politics (e.g., elections and turnover in leadership) that can act as an outlet for social discontent. Finally, these were not all docile societies. For example, there had already been stirrings of protest in Egypt and Tunisia before 2010; in Egypt, in particular, trade unions had become active, defending workers' rights, calling strikes or other forms of industrial actions before 2010. Thus, in several countries there already was an existing organizational foundation for mobilizing and directing action, and experience with collective action. Social media facilitated exchange of ideas and information to aid that mobilization, although social media alone did not provoke or shape protest.

The trigger that turned potential political contention into real social protest and action was Bouazizi's act in December 2010, which he committed in response to his treatment by a local inspector and general discontent with corrupt police. His subsequent death in January 2011 brought together a wide swath of people (rights activists, lawyers, students, trade union representatives, etc.) also disaffected with Tunisia's state. Protests in Tunisia in January 2011 began to spread elsewhere, in part because of a demonstration effect: citizens in one country might view successful protest elsewhere, and sharing similar dissatisfaction, become more likely to take action themselves. Protests in Tunisia quickly spread to Oman, Egypt, Morocco, and Syria, and by February 2011 Hosni Mubarak had stepped down from the presidency of Egypt (a position he had held through rigged elections since the 1980s), and Libya's eventual civil war had begun with conflict in Benghazi. By the end of 2011, the army was maintaining some order in Libya and Egypt, although protests and violence continued to break

out in urban areas and organized protest groups called for the military to transfer political authority to elected bodies and officials.

Except in Syria, where a bloody civil war was dragging out, the politics of many countries of the Arab Spring had settled down to an extent; some had a change in government, while in others (e.g., Algeria) major protest had been repressed but had forced some government concessions (e.g., more social provisions or some political reforms). In Libya and Egypt, social discontent continue to break out on occasion, for example, the attack of the American diplomatic mission in Benghazi in September 2012, or the political crisis in Egypt in 2012 and 2013 during the brief tenure of President Mohamed Morsi, who was overthrown by the military in July 2013. The worst violence of the Arab Spring was in Syria, where Bashar al-Assad responded to protests with violent repression. This transformed the protest into armed resistance, and as a result Syria was engulfed in a civil war that continues to this writing and has so far claimed more than 120 000 victims.

The ultimate effect of Arab Spring is impossible to predict at this point in time, given the newness and rapidity of events. While there have been changes in specific leaders, deeper institutional and structural changes have thus far been far weaker. Militaries continue to play important roles in these countries, and democratic procedures have not yet taken deep roots (although it is far too early to expect such a result). The Syrian civil war also contributed to the creation of the radical group ISIS, which controls territory within Syria and Iraq and has proven to be a major threat to all actors in the region. As for any revolutionary event, Arab Spring has had its romantic portrayals, and the upheaval may ultimately be more superficial than real – but the effects of such revolutions take time to emerge as well. What is clear is that the region is still not entirely stable and more change likely awaits elites and citizens before long.

Abstract

The adherents to Islam, Christianity, and Judaism in the Middle East, while making universal claims for their respective faiths, increasingly recognize the significance of the highly varied local and particular contexts in which their religious symbols, ideas, and practices are understood. This 'local knowledge' also profoundly influences the understanding of ideas and practices considered global and universal. Since the midtwentieth century, the rise of mass education, the proliferation of new communications media, and the greater ease of travel have reconfigured how people think about their own and other religious traditions. These understandings are often distorted, but the fact of their existence is now foregrounded in the consciousness of many believers. Local traditions of belief and practice, earlier taken for granted, increasingly are seen as systems of meaning and action to be articulated and reformed, argued and explained.

The Changed Setting for Religious Pluralism

Islam is the predominant religion in all the countries of the Middle East and North Africa with the obvious exception of Israel, where non-Jews make, primarily Arab Muslims and Christians, up 24% of the population. There are significant Christian and Jewish minorities throughout the region and the lives, doctrines, and practices of the carriers of all these faiths are intricately linked. As with Islam, the practice and understanding of Judaism and Christianity in the region have been highly diverse both in history and in the present, showing an ongoing creative tension between universalism and particularism. The labels 'Muslim', 'Christian', and 'Jew' – not to mention Zoroastrianism in Iran – aggregate the identities of distinct and often autonomous sectarian groups. Christians form significant minorities in Egypt, Lebanon, Iraq, Syria, and Turkey, and European settlers gave the North African states sizable Christian populations until the end of the colonial era in the midtwentieth century.

At the beginning of the twentieth century, Christians and Jews were widely distributed throughout the Middle East and North Africa (Planhol, 1997; Courbage and Fargues, 1997; Sanasarian, 2000). Until the late 1940s in northern Iraq, for example, Sunni Arab Muslims formed a majority of the population in Mosul, with Jews living in both Mosul and surrounding agricultural communities. Shii Turkomen tribes resided in outlying villages, as did communities of Monophysite, Assyrian, and Nestorian Christians. Likewise, Lebanon has 23 recognized Christian and Muslim religious sects, each with separate community identities. At the beginning of the twentieth century there were also thriving Jewish communities distributed widely throughout the region. Some of these remained vital for decades after the declaration of Israel as a state in 1948, and Morocco's Jewish community, although reduced in numbers, remains vital to this day, with Morocco's Jewish heritage formally recognized in its constitution (Gottreich and Schroeter, 2011).

Theologians and ideologues often highlight the distinctiveness of their respective faiths, but Muslims, Christians, and Jews in the region often share implicit background understandings and practices. Sacred spaces shared by all three faiths are found primarily only in Jerusalem and nearby places such as Hebron/al-Khalil, and shared Muslim and Jewish places of regional pilgrimage dot the Moroccan landscape and are equally venerated by Muslims and Jews. Such shared shrines continue to play a vital role in popular belief and practice. Thus in North Africa, festivals for Muslim saints (*musim*s) and pilgrimages to regional shrines (*ziyara*s) have their counterpart in festivals (*hillula*s) for Jewish saints, with some shrines shared by the two faiths (Albera and Couroucli, 2012).

Variations in doctrine, religious practice, and traditions of shared memory also distinguish Muslim communities from one another. These include Sunni Muslims, the Shia (or 'sectarians', who comprise about 10% of Muslims worldwide and are further divided into numerous groups), and Ibadi Muslims of Oman, East Africa, and parts of Tunisia, Libya, and Algeria. The intellectual and educated elite often deny or downplay the significance of local, regional, and sectarian differences in faith and practice, but these practices often are powerfully linked to the local social order and continue to play a major role in the popular imagination.

'Modernity' in the form of uniform state schooling and mass communications often alters these practices, but does not erode them. Nonetheless, rising educational levels and the proliferation of communications media, including satellite television unrestrained by state authorities, are tilting the balance in favor of ideas and practices that can be explained, defended, and foregrounded in public.

Explaining Religious Diversity and Change

Islam, like Judaism and Christianity, is rich and varied in its creativity and cultural expression. It is a challenge for Muslim believers and scholars, both Muslim and non-Muslim, to account for the variations of belief and practice as they have been expressed for over 1400 years in richly diverse cultural and historical traditions. As a response to this complexity, some scholars dismiss as non-Islamic or as incorrect those practices they consider not in accord with 'central' Islamic truths, even though people who hold such beliefs consider themselves fully Muslim. Some deal with these issues by

seeing 'foundation' texts at the core of each religious tradition – the Qur'an in the case of Islam – and then seeing how successive generations understand and articulate them. If such texts and ideas are too closely bound to their original settings, no matter how persuasive for their original audience, they risk failing to attract wider audiences. Such texts must remain relevant to the social and political contexts of succeeding generations.

When first introduced in the late 1940s, the notion of 'Great' and 'Little' traditions offered one way of coming to terms with the universal and the particular in religious expression and practice. The Great/Little tradition contrast rekindled an interest in how popular understandings of religion – the 'little', localized, traditions – were related to elite, literary ones. It also encouraged attention to the specifics of who advocated or explained particular religious orientations and practices, whether they were influential in their own society or marginal, appealing primarily to a particular social group or category (Von Grunebaum, 1955). In some settings, individuals claiming descent from the family of the Prophet Muhammad were given precedence. The concept of the Great/Little tradition encouraged exploring the links among religious ideas and practices, authority, and influence.

Often, however, the concept was employed only to juxtapose statements of 'essential' Islamic principles, as elaborated in standard texts and by educated Muslims, with inventories of local religious practices. For example, the study of trance and possession states (called *zar* cults in the Sudan and East Africa), often indicative of the affective side of religious traditions, was often frequently relegated to the 'little' tradition side of the divide and attributed primarily to women.

Yet such ideas and practices also shed light on ideas of the person and how both women and men in societies with such practices express and explore alternative social realities (Boddy, 1989). Mosque-centered activities such as Friday prayers, almost the exclusive domain of men, often have been seen as part of the 'great' tradition. Women, who often predominate in visits to local shrines and in *zar* cults, are then seen as sustainers of 'local' traditions. This gendered division is made all the more plausible by the fact that until recent decades women had lower levels of education and mobility than men. An alternative explanation, however, is to see mosque-oriented and shrine-oriented practices as integrally complementary, and which must be 'read' together as a unit in order to understand religious practice (Tapper and Tapper, 1987).

In North Africa, Hammoudi (1993) suggested the explanatory utility of linking the canonical Muslim sacrificial feast associated with the annual pilgrimage to Mecca with practices such as *Bûjlûd*, a carnival-like masquerade in Morocco's Berber highlands that follows a few days after the canonical feast. Colonial ethnographers regarded the two events as separate, as do Muslim intellectuals. In the masquerade, a young male villager dons the skin of a sacrificial animal and assumes the character of *Bûjlûd* ('the wearer of the skins'), and with his cohorts cavorts noisily throughout the village, sacrilegiously mocking established religious and social conventions, entering homes, and bantering obscenely with women. Hammoudi argues that the masquerade evokes the contradictions implicit in the cultural classifications that regulate ordinary behavior, including gender roles, directing caricature and self-directed irony against local social hierarchies, tradition, and innovation. The canonical Muslim sacrifice, on the other hand, embodies the ideal community. The canonical sacrifice and masquerade inherently conjoin ritual piety and impiety, embodying an ongoing contest over significance and interpretation in which existing and alternative social orders are embodied and intertwined.

Ritual and Belief in Morocco

In the late 1960s, Morocco became 'good to think with' for understanding religion in complex societies, just as the Trobriand Islands had earlier entered the anthropological canon for understanding exchange systems and India for understanding caste and stratification. The ethnographies of Morocco's colonial era did not lend themselves to comparative studies or lead to disciplinary classics. The publication of Clifford Geertz's *Islam Observed* (1971), originally a series of lectures delivered to historians of religion, marked a breakthrough in linking religious studies in general to the ethnographic study of specific cultural traditions. Geertz took for granted the unity of the Islamic tradition, but emphasized the highly divergent ways in time and space that it articulated with social experience. His point of departure was Islam as experienced, interpreted, and practiced from the fifteenth century to the present in Indonesia and Morocco, the two antipodes of the Muslim majority world. For Geertz, Islamic symbols and meanings are culturally defined and socially shared, like all other systems of meaning. If commonsense gives shared meaning to immediate practical experience, religion offers a higher and more general interpretive order. These two systems of meaning – commonsense and religion – are intricately intertwined, both shaped by historical experience and giving shape to it.
